```

## Arguments

- x** The object on which method dispatch is carried out.  
 For the "formula" method, a formula describing the structure of the plot, which should be of the form  $\sim x \mid g1 * g2 * \dots$ , where  $x$  is a data frame or matrix. Each of  $g1, g2, \dots$  must be either factors or shingles. The conditioning variables  $g1, g2, \dots$  may be omitted.  
 For the `data.frame` methods, a data frame.
- data** For the `formula` methods, an optional data frame in which variables in the formula (as well as `groups` and `subset`, if any) are to be evaluated.
- aspect** aspect ratio of each panel (and subpanel), square by default for `splom`.
- between** to avoid confusion between panels and subpanels, the default is to show the panels of a `splom` plot with space between them.
- panel** For `parallelplot`, this has the usual interpretation, i.e., a function that creates the display within each panel.  
 For `splom`, the terminology is slightly complicated. The role played by the `panel` function in most other high-level functions is played here by the `superpanel` function, which is responsible for the display for each conditional data subset. `panel` is simply an argument to the default `superpanel` function `panel.pairs`,

and is passed on to it unchanged. It is used there to create each pairwise display. See [panel.pairs](#) for more useful options.

|                                                                                                  |                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| superpanel                                                                                       | function that sets up the splom display, by default as a scatterplot matrix.                                                                                                                                                                                                                                                        |
| pscales                                                                                          | a numeric value or a list, meant to be a less functional substitute for the scales argument in <a href="#">xyplot</a> etc. This argument is passed to the superpanel function, and is handled by the default superpanel function <a href="#">panel.pairs</a> . The help page for the latter documents this argument in more detail. |
| varnames                                                                                         | A character or expression vector or giving names to be used for the variables in $x$ . By default, the column names of $x$ .                                                                                                                                                                                                        |
| horizontal.axis                                                                                  | logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).                                                                                                                                                                                                                          |
| auto.key, prepanel, scales, strip, groups, xlab, xlim, ylab, ylim, drop.unused.levels, lattice.c | See <a href="#">xyplot</a>                                                                                                                                                                                                                                                                                                          |

| ...                                                                                              | Further arguments. See corresponding entry in <a href="#">xyplot</a> for non-trivial details.                                                                                                                                                                                                                                       |

## Details

[splom](#) produces Scatter Plot Matrices. The role usually played by [panel](#) is taken over by [superpanel](#), which takes a data frame subset and is responsible for plotting it. It is called with the coordinate system set up to have both x- and y-limits from 0.5 to  $\text{ncol}(z) + 0.5$ . The only built-in option currently available is [panel.pairs](#), which calls a further panel function for each pair  $(i, j)$  of variables in  $z$  inside a rectangle of unit width and height centered at  $c(i, j)$  (see [panel.pairs](#) for details).

Many of the finer customizations usually done via arguments to high level function like [xyplot](#) are instead done by [panel.pairs](#) for [splom](#). These include control of axis limits, tick locations and prepanel calcultions. If you are trying to fine-tune your [splom](#) plot, definitely look at the [panel.pairs](#) help page. The scales argument is usually not very useful in [splom](#), and trying to change it may have undesired effects.

[parallelplot](#) draws Parallel Coordinate Plots. (Difficult to describe, see example.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for [xyplot](#), which should be consulted to learn more detailed usage.

## Value

An object of class "trellis". The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

## Examples

```

super.sym <- trellis.par.get("superpose.symbol")
splom(~iris[1:4], groups = Species, data = iris,
 panel = panel.superpose,
 key = list(title = "Three Varieties of Iris",
 columns = 3,
 points = list(pch = super.sym$pch[1:3],
 col = super.sym$col[1:3]),
 text = list(c("Setosa", "Versicolor", "Virginica"))))

splom(~iris[1:3]|Species, data = iris,
 layout=c(2,2), pscales = 0,
 varnames = c("Sepal\nLength", "Sepal\nWidth", "Petal\nLength"),
 page = function(...) {
 ltext(x = seq(.6, .8, length.out = 4),
 y = seq(.9, .6, length.out = 4),
 labels = c("Three", "Varieties", "of", "Iris"),
 cex = 2)
 })
parallelplot(~iris[1:4] | Species, iris)
parallelplot(~iris[1:4], iris, groups = Species,
 horizontal.axis = FALSE, scales = list(x = list(rot = 90)))

```

---

B\_09\_tmd

*Tukey Mean-Difference Plot*

## Description

**tmd** Creates Tukey Mean-Difference Plots from a trellis object returned by **xyplot**, **qq** or **qqmath**. The **prepanel** and **panel** functions are used as appropriate. The **formula** method for **tmd** is provided for convenience, and simply calls **tmd** on the object created by calling **xyplot** on that formula.

## Usage

```

tmd(object, ...)

S3 method for class 'trellis'
tmd(object,
 xlab = "mean",
 ylab = "difference",
 panel,
 prepanel,
 ...)

prepanel.tmd.qqmath(x,
 f.value = NULL,
 distribution = qnorm,
 qtype = 7,
 groups = NULL,
 subscripts, ...)
panel.tmd.qqmath(x,
 f.value = NULL,
 distribution = qnorm,

```

```

qtype = 7,
groups = NULL,
subscripts, ...,
identifier = "tmd")
panel.tmd.default(x, y, groups = NULL, ...,
 identifier = "tmd")
prepanel.tmd.default(x, y, ...)

```

### Arguments

| xlab                         | x label                                                                                                  |
| ylab                         | y label                                                                                                  |
| panel                        | panel function to be used. See details below.                                                            |
| prepanel                     | prepanel function. See details below.                                                                    |
| f.value, distribution, qtype | see <code>panel.qqmath</code> .                                                                          |
| groups, subscripts           | see <code>xypplot</code> .                                                                               |
| x, y                         | data as passed to panel functions in original call.                                                      |
| ...                          | other arguments                                                                                          |
| identifier                   | A character string that is prepended to the names of grobs that are created by this panel function.      |

### Details

The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows: the new coordinates are given by  $x=(x+y)/2$  and  $y=y-x$ , which are then plotted. The default panel function(s) add a reference line at  $y=0$  as well.

`tmd` acts on the a "trellis" object, not on the actual plot this object would have produced. As such, it only uses the arguments supplied to the panel function in the original call, and completely ignores what the original panel function might have done with this data. `tmd` uses these panel arguments to set up its own scales (using its `prepanel` argument) and display (using `panel`). It is thus important to provide suitable `prepanel` and `panel` functions to `tmd` depending on the original call.

Such functions currently exist for `xypplot`, `qq` (the ones with `default` in their name) and `qqmath`, as listed in the usage section above. These assume the default displays for the corresponding high-level call. If unspecified, the `prepanel` and `panel` arguments default to suitable choices.

`tmd` uses the `update` method for "trellis" objects, which processes all extra arguments supplied to `tmd`.

### Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**B\_11\_oneway***Fit One-way Model*

---

## Description

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using [rfs](#)

## Usage

```
oneway(formula, data, location=mean, spread=function(x) sqrt(var(x)))
```

## Arguments

|                       |                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>  | formula of the form $y \sim x$ where $y$ is the numeric response and $x$ is the grouping factor                                   |
| <code>data</code>     | data frame in which the model is to be evaluated                                                                                  |
| <code>location</code> | function or numeric giving the location statistic to be used for centering the observations, e.g. median, 0 (to avoid centering). |
| <code>spread</code>   | function or numeric giving the spread statistic to be used for scaling the observations, e.g. sd, 1 (to avoid scaling).           |

## Value

A list with components

|                               |                                            |
|-------------------------------|--------------------------------------------|
| <code>location</code>         | vector of locations for each group.        |
| <code>spread</code>           | vector of spreads for each group.          |
| <code>fitted.values</code>    | vector of locations for each observation.  |
| <code>residuals</code>        | residuals ( $y - \text{fitted.values}$ ).  |
| <code>scaled.residuals</code> | residuals scaled by spread for their group |

---

## Description

Initialization of a display device with appropriate graphical parameters.

## Usage

```
trellis.device(device =getOption("device"),
 color = !(dev.name == "postscript"),
 theme = lattice.getOption("default.theme"),
 new = TRUE,
 retain = FALSE,
 ...)

standard.theme(name, color)
canonical.theme(name, color)
col.whitebg()
```

## Arguments

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| device | function (or the name of one as a character string) that starts a device. Admissible values depend on the platform and how R was compiled (see <a href="#">Devices</a> ), but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11", "windows" and "quartz" will be available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| color  | logical, whether the initial settings should be color or black and white. Defaults to FALSE for postscript devices, TRUE otherwise. Note that this only applies to the initial choice of colors, which can be overridden using theme or subsequent calls to <a href="#">trellis.par.set</a> (and by arguments supplied directly in high level calls for some settings).                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| theme  | list of components that changes the settings of the device opened, or, a function that when called produces such a list. The function name can be supplied as a quoted string. These settings are only used to modify the default settings (determined by other arguments), and need not contain all possible parameters.<br><br>A possible use of this argument is to change the default settings by specifying lattice.options(default.theme = "col.whitebg"). For back-compatibility, this is initially (when lattice is loaded) set to getOption(lattice.theme).<br><br>If theme is a function, it will not be supplied any arguments, however, it is guaranteed that a device will already be open when it is called, so one may use .Device inside the function to ascertain what device has been opened. |
| new    | logical flag indicating whether a new device should be started. If FALSE, the options for the current device are changed to the defaults determined by the other arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| retain | logical. If TRUE and a setting for this device already exists, then that is used instead of the defaults for this device. By default, pre-existing settings are overwritten (and lost).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|      |                                                                                                                                                                                                                                                  |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name | name of the device for which the setting is required, as returned by <code>.Device</code>                                                                                                                                                        |
| ...  | additional parameters to be passed to the device function, most commonly <code>file</code> for non-screen devices, as well as <code>height</code> , <code>width</code> , etc. See the help file for individual devices for admissible arguments. |

## Details

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable “settings” list. This functionality is analogous to `par` for standard R graphics and, together with `lattice.options`, mostly supplants it (`par` settings are mostly ignored by Lattice). Unlike `par`, Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device). `standard.theme` and `col.whitebg` produce predefined settings (a.k.a. themes), while `trellis.device` provides a high level interface to control which “theme” will be in effect when a new device is opened. `trellis.device` is called automatically when a “trellis” object is plotted, and the defaults can be used to provide sufficient control, so in a properly configured system it is rarely necessary for the user to call `trellis.device` explicitly.

The `standard.theme` function is intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) which were used as defaults prior to R 2.3.0. However, these defaults are not always appropriate, due to the variety of platforms and hardware settings on which R is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, a “safe” default is used for all devices from R 2.3.0 onwards. The old behaviour can be reinstated by setting `standard.theme` as the default theme argument, e.g. by putting `lattice.options(default.theme = "standard.theme")` in a startup script (see the entry for `theme` above for details).

## Value

`standard.theme` returns a list of components defining graphical parameter settings for Lattice displays. It is used internally in `trellis.device`, and can also be used as the `theme` argument to `trellis.par.set`, or even as `theme` in `trellis.device` to use the defaults for another device. `canonical.theme` is an alias for `standard.theme`.

`col.whitebg` returns a similar (but smaller) list that is suitable as the `theme` argument to `trellis.device` and `trellis.par.set`. It contains settings values which provide colors suitable for plotting on a white background. Note that the name `col.whitebg` is somewhat of a misnomer, since it actually sets the background to transparent rather than white.

## Note

Earlier versions of `trellis.device` had a `bg` argument to set the background color, but this is no longer supported. If supplied, the `bg` argument will be passed on to the `device` function; however, this will have no effect on the Trellis settings. It is rarely meaningful to change the background alone; if you feel the need to change the background, consider using the `theme` argument instead.

[trellis.par.get](#) and [trellis.par.set](#) can be used to query and modify the settings *after* a device has been initialized. The `par.settings` argument to high level functions, described in [xyplot](#), can be used to attach transient settings to a "trellis" object.

`C_02_trellis.par.get`    *Graphical Parameters for Trellis Displays*

**Description**

Functions used to query, display and modify graphical parameters for fine control of Trellis displays. Modifications are made to the settings for the currently active device only.

**Usage**

```
trellis.par.set(name, value, ..., theme, warn = TRUE, strict = FALSE)
trellis.par.get(name = NULL)
show.settings(x = NULL)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>   | A character string giving the name of a component. If unspecified in <code>trellis.par.get()</code> , the return value is a named list containing all the current settings (this can be used to get the valid values for <code>name</code> ).                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>value</code>  | a list giving the desired value of the component. Components that are already defined as part of the current settings but are not mentioned in <code>value</code> will remain unchanged.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>theme</code>  | a list describing how to change the settings, similar to what is returned by <code>trellis.par.get()</code> . This is purely for convenience, allowing multiple calls to <code>trellis.par.set</code> to be condensed into one. The name of each component must be a valid name as described above, with the corresponding value a valid value as described above.<br>As in <a href="#">trellis.device</a> , <code>theme</code> can also be a function that produces such a list when called. The function name can be supplied as a quoted string.                                                                                   |
| <code>...</code>    | Multiple settings can be specified in <code>name = value</code> form. Equivalent to calling with <code>theme = list(...)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>warn</code>   | A logical flag, indicating whether a warning should be issued when <code>trellis.par.get</code> is called when no graphics device is open.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>strict</code> | Usually a logical flag, indicating whether the <code>value</code> should be interpreted strictly. Usually, assignment of <code>value</code> to the corresponding named component is fuzzy in the sense that sub-components that are absent from <code>value</code> but not currently <code>NULL</code> are retained. By specifying <code>strict = TRUE</code> , such values will be removed.<br>An even stricter interpretation is allowed by specifying <code>strict</code> as a numeric value larger than 1. In that case, top-level components not specified in the call will also be removed. This is primarily for internal use. |

- x optional list of components that change the settings (any valid value of theme). These are used to modify the current settings (obtained by `trellis.par.get`) before they are displayed.

## Details

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like `x11` and `windows`, one for black and white plots (mostly useful for `postscript`) and one for color printers (`color postscript, pdf`).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a `postscript` device will not alter the `x11` settings, which will remain in effect whenever an `x11` device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently ACTIVE device.

`trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the `name` argument present, it returns that component only. `trellis.par.get` sets the value of the `name` component of the current active device settings to `value`.

`trellis.par.get` is usually used inside `trellis` functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```
add.line <- trellis.par.get("add.line")
```

```
add.line$col <- "red"
```

```
trellis.par.set("add.line", add.line)
```

More convenient (but not S compatible) ways to do this are

```
trellis.par.set(list(add.line = list(col = "red")))
```

and

```
trellis.par.set(add.line = list(col = "red"))
```

The actual list of the components in `trellis.settings` has not been finalized, so I'm not attempting to list them here. The current value can be obtained by `print(trellis.par.get())`. Most names should be self-explanatory.

`show.settings` provides a graphical display summarizing some of the values in the current settings.

## Value

`trellis.par.get` returns a list giving parameters for that component. If `name` is missing, it returns the full list.

Most of the settings are graphical parameters that control various elements of a lattice plot. For details, see the examples below. The more unusual settings are described here.

**grid.pars** Grid graphical parameters that are in effect globally unless overridden by specific settings.

**fontsize** A list of two components (each a numeric scalar), **text** and **points**, for text and symbols respectively.

**clip** A list of two components (each a character string, either "on" or "off"), **panel** and **strip**.

**axis.components**

**layout.heights**

**layout.widths**

### Note

In some ways, **trellis.par.get** and **trellis.par.set** together are a replacement for the **par** function used in traditional R graphics. In particular, changing **par** settings has little (if any) effect on lattice output. Since lattice plots are implemented using Grid graphics, its parameter system *does* have an effect unless overridden by a suitable lattice parameter setting. Such parameters can be specified as part of a lattice theme by including them in the **grid.pars** component (see **gpar** for a list of valid parameter names).

### Examples

```
show.settings()

tp <- trellis.par.get()

unusual <- c("grid.pars", "fontsize", "clip", "axis.components",
 "layout.heights", "layout.widths")

for (u in unusual) tp[[u]] <- NULL
names.tp <- lapply(tp, names)
unames <- sort(unique(unlist(names.tp)))
ans <- matrix(0, nrow = length(names.tp), ncol = length(unames))
rownames(ans) <- names(names.tp)
colnames(ans) <- unames
for (i in seq(along = names.tp))
 ans[i,] <- as.numeric(unames %in% names.tp[[i]])
ans <- ans[, order(-colSums(ans))]
ans <- ans[order(rowSums(ans)),]
ans[ans == 0] <- NA

levelplot(t(ans), colorkey = FALSE,
 scales = list(x = list(rot = 90)),
 panel = function(x, y, z, ...) {
 panel.abline(v = unique(as.numeric(x)),
 h = unique(as.numeric(y)),
 col = "darkgrey")
 panel.xyplot(x, y, pch = 16 * z, ...)
```

```

},
xlab = "Graphical parameters",
ylab = "Setting names")

```

C\_03\_simpleTheme      *Function to generate a simple theme*

## Description

Simple interface to generate a list appropriate as a theme, typically used as the `par.settings` argument in a high level call

## Usage

```
simpleTheme(col, alpha,
 cex, pch, lty, lwd, font, fill, border,
 col.points, col.line,
 alpha.points, alpha.line)
```

## Arguments

|                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>col, col.points, col.line</code>       | A color specification. <code>col</code> is used for components <code>"plot.symbol"</code> , <code>"plot.line"</code> , <code>"plot.polygon"</code> , <code>"superpose.symbol"</code> , <code>"superpose.line"</code> , and <code>"superpose.polygon"</code> . <code>col.points</code> overrides <code>col</code> , but is used only for <code>"plot.symbol"</code> and <code>"superpose.symbol"</code> . Similarly, <code>col.line</code> overrides <code>col</code> for <code>"plot.line"</code> and <code>"superpose.line"</code> . The arguments can be vectors, but only the first component is used for scalar targets (i.e., the ones without <code>"superpose"</code> in their name). |
| <code>alpha, alpha.points, alpha.line</code> | A numeric alpha transparency specification. The same rules as <code>col</code> , etc., apply.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>cex, pch, font</code>                  | Parameters for points. Applicable for components <code>plot.symbol</code> (for which only the first component is used) and <code>superpose.symbol</code> (for which the arguments can be vectors).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>lty, lwd</code>                        | Parameters for lines. Applicable for components <code>plot.line</code> (for which only the first component is used) and <code>superpose.line</code> (for which the arguments can be vectors).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>fill</code>                            | <code>fill</code> color, applicable for components <code>plot.symbol</code> , <code>plot.polygon</code> , <code>superpose.symbol</code> , and <code>superpose.polygon</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>border</code>                          | <code>border</code> color, applicable for components <code>plot.polygon</code> and <code>superpose.polygon</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

The appearance of a lattice display depends partly on the “theme” active when the display is plotted (see `trellis.device` for details). This theme is used to obtain defaults for various graphical parameters, and in particular, the `auto.key` argument works on the premise that the same source is used for both the actual graphical encoding and the legend. The easiest way to specify custom settings for a particular display is to use the `par.settings` argument, which is usually tedious to

construct as it is a nested list. The `simpleTheme` function can be used in such situations as a wrapper that generates a suitable list given parameters in simple name=value form, with the nesting made implicit. This is less flexible, but straightforward and sufficient in most situations.

### Value

A list that would work as the theme argument to `trellis.device` and `trellis.par.set`, or as the `par.settings` argument to any high level lattice function such as `xyplot`.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>, based on a suggestion from John Maindonald.

### See Also

`trellis.device`, `xyplot`, `Lattice`

### Examples

```
str(simpleTheme(pch = 16))

dotplot(variety ~ yield | site, data = barley, groups = year,
 auto.key = list(space = "right"),
 par.settings = simpleTheme(pch = 16),
 xlab = "Barley Yield (bushels/acre) ",
 aspect=0.5, layout = c(1,6))
```

### Description

Functions to handle settings used by lattice. Their main purpose is to make code maintainance easier, and users normally should not need to use these functions. However, fine control at this level maybe useful in certain cases.

### Usage

```
lattice.options(...)
latticegetOption(name)
```

### Arguments

|                   |                                                                                                                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code> | character giving the name of a setting                                                                                                                                                                                                                                                      |
| <code>...</code>  | new options can be defined, or existing ones modified, using one or more arguments of the form <code>name = value</code> or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments. |

## Details

These functions are modeled on `options` and `getOption`, and behave similarly for the most part. Some of the available components are documented here, but not all. The purpose of the ones not documented are either fairly obvious, or not of interest to the end-user.

`panel.error` A function, or `NULL`. If the former, every call to the panel function will be wrapped inside `tryCatch` with the specified function as an error handler. The default is to use the `panel.error` function. This prevents the plot from failing due to errors in a single panel, and leaving the grid operations in an unmanageable state. If set to `NULL`, errors in panel functions will not be caught using `tryCatch`.

`save.object` Logical flag indicating whether a "trellis" object should be saved when plotted for subsequent retrieval and further manipulation. Defaults to `TRUE`.

`layout.widths`, `layout.heights` Controls details of the default space allocation in the grid layout created in the course of plotting a "trellis" object. Each named component is a list of arguments to the `grid` function `unit` (`x`, `units`, and optionally `data`).

Usually not of interest to the end-user, who should instead use the similarly named component in the graphical settings, modifiable using `trellis.par.set`.

`drop.unused.levels` A list of two components named `cond` and `data`, both logical flags. The flags indicate whether the unused levels of factors (conditioning variables and primary variables respectively) will be dropped, which is usually relevant when a subsetting operation is performed or an 'interaction' is created. See `xyplot` for more details. Note that this does not control dropping of levels of the 'groups' argument.

`legend.bbox` A character string, either "full" or "panel". This determines the interpretation of `x` and `y` when `space="inside"` in `key` (determining the legend; see `xyplot`): either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

`default.args` A list giving default values for various standard arguments: `as.table`, `aspect`, `between`, `skip`, `strip`, `xscale.components`, `yscale.components`, and `axis`.

`highlight.gpar` A list giving arguments to `gpar` used to highlight a viewport chosen using `trellis.focus`.

`banking` The banking function. See `banking`.

`axis.padding` List with components named "numeric" and "factor", both scalar numbers. Panel limits are extended by this amount, to provide padding for numeric and factor scales respectively. The value for numeric is multiplicative, whereas factor is additive.

`skip.boundary.labels` Numeric scalar between 0 and 1. Tick marks that are too close to the limits are not drawn unless explicitly requested. The limits are contracted by this proportion, and anything outside is skipped.

`interaction.sep` The separator for creating interactions with the extended formula interface (see `xyplot`).

`axis.units` List determining default units for axis components. Should not be of interest to the end-user.

In addition, there is an option for the default prepanel and panel function for each high-level function; e.g., `panel.xyplot` and `prepanel.default.xyplot` for `xyplot`. The options for the others have similarly patterned names.

## Value

`lattice.getOption` returns the value of a single component, whereas `lattice.options` always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by `lattice.options`. If called without any arguments, the full list is returned.

**C\_05\_print.trellis**      *Plot and Summarize Trellis Objects*

**Description**

The print and plot methods produce a graph from a "trellis" object. The print method is necessary for automatic plotting. plot method is essentially an alias, provided for convenience. The summary method gives a textual summary of the object. dim and dimnames describe the cross-tabulation induced by conditioning. panel.error is the default handler used when an error occurs while executing the panel function.

**Usage**

```
S3 method for class 'trellis'
plot(x, position, split,
 more = FALSE, newpage = TRUE,
 packet.panel = packet.panel.default,
 draw.in = NULL,
 panel.height = latticegetOption("layout.heights")$panel,
 panel.width = latticegetOption("layout.widths")$panel,
 save.object = latticegetOption("save.object"),
 panel.error = latticegetOption("panel.error"),
 prefix,
 ...)
S3 method for class 'trellis'
print(x, ...)

S3 method for class 'trellis'
summary(object, ...)

S3 method for class 'trellis'
dim(x)
S3 method for class 'trellis'
dimnames(x)

panel.error(e)
```

### Arguments

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, object</code>                 | an object of class "trellis"                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>position</code>                  | a vector of 4 numbers, typically <code>c(xmin, ymin, xmax, ymax)</code> that give the lower-left and upper-right corners of a rectangle in which the Trellis plot of <code>x</code> is to be positioned. The coordinate system for this rectangle is [0-1] in both the x and y directions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>split</code>                     | a vector of 4 integers, <code>c(x,y,nx,ny)</code> , that says to position the current plot at the x,y position in a regular array of nx by ny plots. (Note: this has origin at top left)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>more</code>                      | A logical specifying whether more plots will follow on this page.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>newpage</code>                   | A logical specifying whether the plot should be on a new page. This option is specific to lattice, and is useful for including lattice plots in an arbitrary grid viewport (see the details section).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>packet.panel</code>              | a function that determines which packet (data subset) is plotted in which panel. Panels are always drawn in an order such that columns vary the fastest, then rows and then pages. This function determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. By default, the association is determined by matching panel order with packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. This association rule is encoded in the default, namely the function <code>packet.panel.default</code> , whose help page details the arguments supplied to whichever function is specified as the <code>packet.panel</code> argument.                                 |
| <code>draw.in</code>                   | An optional (grid) viewport (used as the <code>name</code> argument in <code>downViewport</code> ) in which the plot is to be drawn. If specified, the <code>newpage</code> argument is ignored. This feature is not well-tested.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>panel.width, panel.height</code> | lists with 2 components, that should be valid <code>x</code> and <code>units</code> arguments to <code>unit()</code> (the <code>data</code> argument cannot be specified currently, but can be considered for addition if needed). The resulting <code>unit</code> object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.<br><br>Note that this option should not be used in conjunction with non-default values of the <code>aspect</code> argument in the original high level call (no error will be produced, but the resulting behaviour is undefined). |
| <code>save.object</code>               | logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel's data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the <code>update</code> method on the current plot, even if it was not assigned to a variable explicitly. For more details, see <code>trellis.focus</code> .                                                                                                                                                                                                                                                                                                              |
| <code>panel.error</code>               | a function, or a character string naming a function, that is to be executed when an error occurs during the execution of the panel function. The error is caught (using <code>tryCatch</code> ) and supplied as the only argument to <code>panel.error</code> . The default behaviour (implemented as the <code>panel.error</code> function) is to print the corresponding error message in the panel and continue. To stop execution on error, use <code>panel.error = stop</code> .                                                                                                                                                                                                                                                                                                                  |

Normal error recovery and debugging tools are unhelpful when `tryCatch` is used. `tryCatch` can be completely bypassed by setting `panel.error` to `NULL`.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>prefix</code> | A character string acting as a prefix identifying the plot of a "trellis" object, primarily used in constructing viewport and grob names, to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (specifically, "plot_01", "plot_02", etc.). If supplied explicitly, this must be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently ":"). |
| <code>e</code>      | an error condition caught by <code>tryCatch</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>...</code>    | extra arguments, ignored by the <code>print</code> method. All arguments to the <code>plot</code> method are passed on to the <code>print</code> method.                                                                                                                                                                                                                                                                                                                                                                                     |

## Details

This is the default print method for objects of class "trellis", produced by calls to functions like `xypplot`, `bwplot` etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments `split` and `position`.

When `newpage = FALSE`, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The `draw.in` argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in `x` (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.

Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see `trellis.focus`.

## Note

Unlike S-PLUS, trying to position a multipage display (using `position` and/or `split`) will mess things up.

`Lattice`, `unit`, `update.trellis`, `trellis.focus`, `packet.panel.default`

## Examples

```
p11 <- histogram(~ height | voice.part, data = singer, xlab="Height")
p12 <- densityplot(~ height | voice.part, data = singer, xlab = "Height")
p2 <- histogram(~ height, data = singer, xlab = "Height")

simple positioning by split
print(p11, split=c(1,1,1,2), more=TRUE)
print(p2, split=c(1,2,1,2))
```

```

Combining split and position:
print(p11, position = c(0,0,.75,.75), split=c(1,1,1,2), more=TRUE)
print(p12, position = c(0,0,.75,.75), split=c(1,2,1,2), more=TRUE)
print(p2, position = c(.5,.75,1,1), more=FALSE)

Using seekViewport

repeat same plot, with different polynomial fits in each panel
xyplot(Armed.Forces ~ Year, longley, index.cond = list(rep(1, 6)),
 layout = c(3, 2),
 panel = function(x, y, ...)
{
 panel.xyplot(x, y, ...)
 fm <- lm(y ~ poly(x, panel.number()))
 llines(x, predict(fm))
})

Not run:
grid::seekViewport(trellis.vpname("panel", 1, 1))
cat("Click somewhere inside the first panel:\n")
ltext(grid::grid.locator(), lab = "linear")

End(Not run)

grid::seekViewport(trellis.vpname("panel", 1, 1))
grid::grid.text("linear")

grid::seekViewport(trellis.vpname("panel", 2, 1))
grid::grid.text("quadratic")

grid::seekViewport(trellis.vpname("panel", 3, 1))
grid::grid.text("cubic")

grid::seekViewport(trellis.vpname("panel", 1, 2))
grid::grid.text("degree 4")

grid::seekViewport(trellis.vpname("panel", 2, 2))
grid::grid.text("degree 5")

grid::seekViewport(trellis.vpname("panel", 3, 2))
grid::grid.text("degree 6")

```

## Description

Update method for objects of class “trellis”, and a way to retrieve the last printed trellis object (that was saved).

## Usage

```

S3 method for class 'trellis'
update(object,

```

```

```

### Arguments

|                                                                                                               |                                                                                                                                                           |
|---------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object, x</code>                                                                                        | The object to be updated, of class "trellis".                                                                                                             |
| <code>i, j</code>                                                                                             | indices to be used. Names are not currently allowed.                                                                                                      |
| <code>drop</code>                                                                                             | logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were FALSE.                                        |
| <code>panel, aspect, as.table, between, key, auto.key, legend, layout, main, page, par.strip.text, pre</code> | arguments that will be used to update <code>object</code> . See details below.                                                                            |
| <code>prefix</code>                                                                                           | A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. |

Defaults to the value appropriate for the last "trellis" object printed. See [trellis.focus](#).

## Details

All high level lattice functions such as `xyplot` produce an object of (S3) class "trellis", which is usually displayed by its `print` method. However, the object itself can be manipulated and modified to a large extent using the `update` method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the `update` method as well, with some exceptions. Generally speaking, anything that would needs to change the data within each panel is a no-no (this includes the `formula`, `data`, `groups`, `subscripts` and `subset`). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by `update`, but the ones listed above should work. The purpose of these arguments are described in the help page for [xyplot](#). Any other argument is added to the list of arguments to be passed to the `panel` function. Because of their somewhat special nature, updates to objects produced by `cloud` and `wireframe` do not work very well yet.

The "[" method is a convenient shortcut for updating `index.cond`. The `t` method is a convenient shortcut for updating `perm.cond` in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching ('transposing') their order.

The `print` method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, `trellis.last.object` can retrieve it. By default, the last object plotted is retrieved, but if multiple objects are plotted on the current page, then others can be retrieved using the appropriate `prefix` argument. If [trellis.last.object](#) is called with arguments, these are used to update the retrieved object before returning it.

## Value

An object of class `trellis`, by default plotted by `print.trellis`. `trellis.last.object` returns `NULL` is no saved object is available.

## Examples

```
spots <- by(sunspots, gl(235, 12, labels = 1749:1983), mean)
old.options <- lattice.options(save.object = TRUE)
xyplot(spots ~ 1749:1983, xlab = "", type = "l",
 scales = list(x = list(alternating = 2)),
 main = "Average Yearly Sunspots")
update(trellis.last.object(), aspect = "xy")
trellis.last.object(xlab = "Year")
lattice.options(old.options)
```

**C\_07\_shingles**                  *shingles*

### Description

Functions to handle shingles

### Usage

```
shingle(x, intervals=sort(unique(x)))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)

S3 method for class 'shingle'
plot(x, panel, xlab, ylab, ...)

S3 method for class 'shingle'
print(x, showValues = TRUE, ...)

S3 method for class 'shingleLevel'
as.character(x, ...)

S3 method for class 'shingleLevel'
print(x, ...)

S3 method for class 'shingle'
summary(object, showValues = FALSE, ...)

S3 method for class 'shingle'
x[subset, drop = FALSE]
as.factorOrShingle(x, subset, drop)
```

### Arguments

|                          |                                                                                                                                                                                             |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>                 | numeric variable or R object, shingle in plot.shingle and x[ ]. An object (list of intervals) of class "shingleLevel" in print.shingleLevel                                                 |
| <b>object</b>            | shingle object to be summarized                                                                                                                                                             |
| <b>showValues</b>        | logical, whether to print the numeric part. If FALSE, only the intervals are printed                                                                                                        |
| <b>intervals</b>         | numeric vector or matrix with 2 columns                                                                                                                                                     |
| <b>subset</b>            | logical vector                                                                                                                                                                              |
| <b>drop</b>              | whether redundant shingle levels are to be dropped                                                                                                                                          |
| <b>panel, xlab, ylab</b> | standard Trellis arguments (see <a href="#">xyplot</a> )                                                                                                                                    |
| <b>...</b>               | other arguments, passed down as appropriate. For example, extra arguments to equal.count are passed on to co.intervals. graphical parameters can be passed as arguments to the plot method. |

## Details

A shingle is a data structure used in Trellis, and is a generalization of factors to ‘continuous’ variables. It consists of a numeric vector along with some possibly overlapping intervals. These intervals are the ‘levels’ of the shingle. The `levels` and `nlevels` functions, usually applicable to factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of `levels()` applied to a shingle. For use in labelling, the `as.character` method can be used to convert levels of a shingle to character strings.

`equal.count` converts `x` to a shingle using the equal count algorithm. This is essentially a wrapper around `co.intervals`. All arguments are passed to `co.intervals`.

`shingle` creates a shingle using the given `intervals`. If `intervals` is a vector, these are used to form 0 length intervals.

`as.shingle` returns `shingle(x)` if `x` is not a shingle.

`is.shingle` tests whether `x` is a shingle.

`plot.shingle` displays the ranges of shingles via rectangles. `print.shingle` and `summary.shingle` describe the shingle object.

## Value

`x$intervals` for `levels.shingle(x)`, logical for `is.shingle`, an object of class “trellis” for `plot` (printed by default by `print.trellis`), and an object of class “shingle” for the others.

## Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

## Examples

```
z <- equal.count(rnorm(50))
plot(z)
print(z)
print(levels(z))
```

## Description

Produces (and possibly draws) a Grid frame grob which is a colorkey that can be placed in other Grid plots. Used in `levelplot`

## Usage

```
draw.colorkey(key, draw=FALSE, vp=NULL)
```

**Arguments**

|      |                                                                                                                                                                  |

|----------------|------------------------------------------------------------------------------------------|
| D_level.colors | <i>A function to compute false colors representing a numeric or categorical variable</i> |
|----------------|------------------------------------------------------------------------------------------|

---

## Description

Calculates false colors from a numeric variable (including factors, using their numeric codes) given a color scheme and breakpoints.

## Usage

```
level.colors(x, at, col.regions, colors = TRUE, ...)
```

## Arguments

|             |                                                                                                                                                                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | A numeric or <a href="#">factor</a> variable.                                                                                                                                                                                                           |
| at          | A numeric variable of breakpoints defining intervals along the range of x.                                                                                                                                                                              |
| col.regions | A specification of the colors to be assigned to each interval defined by at. This could be either a vector of colors, or a function that produces a vector of colors when called with a single argument giving the number of colors. See details below. |
| colors      | logical indicating whether colors should be computed and returned. If FALSE, only the indices representing which interval (among those defined by at) each value in x falls into is returned.                                                           |
| ...         | Extra arguments, ignored.                                                                                                                                                                                                                               |

## Details

If at has length n, then it defines n-1 intervals. Values of x outside the range of at are not assigned to an interval, and the return value is NA for such values.

Colors are chosen by assigning a color to each of the n-1 intervals. If col.regions is a palette function (such as [topo.colors](#), or the result of calling [colorRampPalette](#)), it is called with n-1 as an argument to obtain the colors. Otherwise, if there are exactly n-1 colors in col.regions, these get assigned to the intervals. If there are fewer than n-1 colors, col.regions gets recycled. If there are more, a more or less equally spaced (along the length of col.regions) subset is chosen.

## Value

A vector of the same length as x. Depending on the colors argument, this could be either a vector of colors (in a form usable by R), or a vector of integer indices representing which interval the values of x fall in.

## See Also

[levelplot](#), [colorRampPalette](#).

## Examples

```
depth.col <-
 with(quakes,
 level.colors(depth, at = do.breaks(range(depth), 30),
 col.regions = terrain.colors))

xyplot(lat ~ long | equal.count(stations), quakes,
 strip = strip.custom(var.name = "Stations"),
 colours = depth.col,
 panel = function(x, y, colours, subscripts, ...) {
 panel.xyplot(x, y, pch = 21, col = "transparent",
 fill = colours[subscripts], ...)
 })

```

**D\_make.groups**

*Grouped data from multiple vectors*

## Description

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.

## Usage

```
make.groups(...)
```

## Arguments

|     |                                                                                                                                                               |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ... | one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows. |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Value

When all the input arguments are vectors, a data frame with two columns

|       |                                                                       |
|-------|-----------------------------------------------------------------------|
| data  | all the vectors supplied, concatenated                                |
| which | factor indicating which vector the corresponding data value came from |

When all the input arguments are data frames, the result of `rbind` applied to them, along with an additional which column as described above.

## Examples

```
sim.dat <-
 make.groups(uniform = runif(200),
 exponential = rexp(175),
 lognormal = rlnorm(150),
 normal = rnorm(125))
qqmath(~ data | which, sim.dat, scales = list(y = "free"))
```

D\_simpleKey

*Function to generate a simple key*

## Description

Simple interface to generate a list appropriate for `draw.key`

## Usage

```
simpleKey(text, points = TRUE,
 rectangles = FALSE,
 lines = FALSE,
 col, cex, alpha, font,
 fontface, fontfamily,
 lineheight, ...)
```

## Arguments

|                                                                      |                                                                                                                                                          |
|----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>text</code>                                                    | character or expression vector, to be used as labels for levels of the grouping variable                                                                 |
| <code>points</code>                                                  | logical                                                                                                                                                  |
| <code>rectangles</code>                                              | logical                                                                                                                                                  |
| <code>lines</code>                                                   | logical                                                                                                                                                  |
| <code>col, cex, alpha, font, fontface, fontfamily, lineheight</code> | Used as top-level components of the list produced, to be used for the text labels.<br>Defaults to the values in <code>trellis.par.get("add.text")</code> |
| <code>...</code>                                                     | further arguments added to the list, eventually passed to <code>draw.key</code>                                                                          |

## Details

A lattice plot can include a legend (key) if an appropriate list is specified as the `key` argument to a high level Lattice function such as `xyplot`. This key can be very flexible, but that flexibility comes at a cost: this list needs to be fairly complicated even in simple situations. `simpleKey` is designed as a useful shortcut in the common case of a key drawn in conjunction with a grouping variable, using the default graphical settings.

The `simpleKey` function produces a suitable key argument using a simpler interface. The resulting list will use the `text` argument as a text component, along with at most one set each of `points`, `rectangles`, and `lines`. The number of entries (rows) in the key will be the length of the `text` component. The graphical parameters for the additional components will be derived from the default graphical settings (wherein lies the simplification, as otherwise these would have to be provided explicitly).

Calling `simpleKey` directly is usually unnecessary. It is most commonly invoked (during the plotting of the "trellis" object) when the `auto.key` argument is supplied in a high-level plot with

a groups argument. In that case, the text argument of simpleKey defaults to levels(groups), and the defaults for the other arguments depend on the relevant high-level function. Note that these defaults can be overridden by supplying auto.key as a list containing the replacement values.

### Value

A list that would work as the key argument to [xyplot](#), etc.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

### See Also

**D\_strip.default**

*Default Trellis Strip Function*

### Description

`strip.default` is the function that draws the strips by default in Trellis plots. Users can write their own strip functions, but most commonly this involves calling `strip.default` with a slightly different arguments. `strip.custom` provides a convenient way to obtain new strip functions that differ from `strip.default` only in the default values of certain arguments.

### Usage

```
strip.default(which.given,
 which.panel,
 var.name,
 factor.levels,
 shingle.intervals,
 strip.names = c(FALSE, TRUE),
 strip.levels = c(TRUE, FALSE),
 sep = " : ",
 style = 1,
 horizontal = TRUE,
 bg = trellis.par.get("strip.background")$col[which.given],
 fg = trellis.par.get("strip.shingle")$col[which.given],
 par.strip.text = trellis.par.get("add.text"))
strip.custom(...)
```

### Arguments

- |                          |                                                                                                                                                                                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>which.given</code> | integer index specifying which of the conditioning variables this strip corresponds to.                                                                                                                                                                                                                                        |
| <code>which.panel</code> | vector of integers as long as the number of conditioning variables. The contents are indices specifying the current levels of each of the conditioning variables (thus, this would be unique for each distinct packet). This is identical to the return value of <a href="#">which.packet</a> , which is a more accurate name. |

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>var.name</code>          | vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of <code>strip.names</code> and <code>style</code> (see below). By default, the names are shown for shingles, but not for factors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>factor.levels</code>     | vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with <code>which.given</code> . Whether these levels are shown on the strip depends on the values of <code>strip.levels</code> and <code>style</code> (see below). <code>factor.levels</code> may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in <code>par.strip.text</code> (see <a href="#">xyplot</a> )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>shingle.intervals</code> | if the current strip corresponds to a shingle, this should be a 2-column matrix giving the levels of the shingle. (of the form that would be produced by <b>printing</b> <code>levels(shingle)</code> ). Otherwise, it should be <code>NULL</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>strip.names</code>       | a logical vector of length 2, indicating whether or not the name of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively. This argument is ignored for a factor when <code>style</code> is not one of 1 and 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>strip.levels</code>      | a logical vector of length 2, indicating whether or not the level of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>sep</code>               | character or expression, serving as a separator if the name and level are both to be shown.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>style</code>             | integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how the current level of a factor is encoded. Ignored for shingles (actually, when <code>shingle.intervals</code> is non-null).<br><br>The best way to find out what effect the value of <code>style</code> has is to try them out. Here is a short description: for a style value of 1, the strip is colored in the background color with the strip text (as determined by other arguments) centered on it. A value of 3 is the same, except that a part of the strip is colored in the foreground color, indicating the current level of the factor. For styles 2 and 4, the part corresponding to the current level remains colored in the foreground color, however, for style = 2, the remaining part is not colored at all, whereas for 4, it is colored with the background color. For both these, the names of all the levels of the factor are placed on the strip from left to right. Styles 5 and 6 produce the same effect (they are subtly different in S, this implementation corresponds to 5), they are similar to style 1, except that the strip text is not centered, it is instead positioned according to the current level.<br><br>Note that unlike S-PLUS, the default value of <code>style</code> is 1. <code>strip.names</code> and <code>strip.levels</code> have no effect if <code>style</code> is not 1 or 3. |
| <code>horizontal</code>        | logical, specifying whether the labels etc should be horizontal. <code>horizontal=FALSE</code> is useful for strips on the left of panels using <code>strip.left=TRUE</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>par.strip.text</code>    | list with parameters controlling the text on each strip, with components <code>col</code> , <code>cex</code> , <code>font</code> , etc.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>bg</code>                | strip background color.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>fg</code>                | strip foreground color.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

... arguments to be passed on to `strip.default`, overriding whatever value it would have normally assumed

## Details

default strip function for trellis functions. Useful mostly because of the `style` argument — non-default styles are often more informative, especially when the names of the levels of the factor `x` are small. Traditional use is as `strip = function(...) strip.default(style=2,...)`, though this can be simplified by the use of `strip.custom`.

## Value

`strip.default` is called for its side-effect, which is to draw a strip appropriate for multi-panel Trellis conditioning plots. `strip.custom` returns a function that is similar to `strip.default`, but with different defaults for the arguments specified in the call.

## Examples

```
Traditional use
xyplot(Petal.Length ~ Petal.Width | Species, iris,
 strip = function(..., style) strip.default(..., style = 4))

equivalent call using strip.custom
xyplot(Petal.Length ~ Petal.Width | Species, iris,
 strip = strip.custom(style = 4))

xyplot(Petal.Length ~ Petal.Width | Species, iris,
 strip = FALSE,
 strip.left = strip.custom(style = 4, horizontal = FALSE))
```

## Description

This class of objects is returned by high level lattice functions, and is usually plotted by default by its [print](#) method.

## Details

A trellis object, as returned by high level lattice functions like [xyplot](#), is a list with the "class" attribute set to "trellis". Many of the components of this list are simply the arguments to the high level function that produced the object. Among them are: `as.table`, `layout`, `page`, `panel`, `prepanel`, `main`, `sub`, `par.strip.text`, `strip`, `skip`, `xlab` `ylab`, `par.settings`, `lattice.options` and `plot.args`. Some other typical components are:

formula the Trellis formula used in the call  
index.cond list with index for each of the conditioning variables  
perm.cond permutation of the order of the conditioning variables  
aspect.fill logical, whether aspect is "fill"  
aspect.ratio numeric, aspect ratio to be used if aspect.fill is FALSE  
call call that generated the object.  
condlevels list with levels of the conditioning variables  
legend list describing the legend(s) to be drawn  
panel.args a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.  
panel.args.common a list containing the arguments common to all the panel functions in name=value form  
x.scales list describing x-scale, can consist of several other lists, paralleling panel.args, if x-relation is not "same"  
y.scales list describing y-scale, similar to x.scales  
x.between numeric vector of interpanel x-space  
y.between numeric vector of interpanel y-space  
x.limits numeric vector of length 2 or list, giving x-axis limits  
y.limits similar to x.limits  
packet.sizes array recording the number of observations in each packet

### Description

The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.

**Usage**

```

panel.identify(x, y = NULL,
 subscripts = seq_along(x),
 labels = subscripts,
 n = length(x), offset = 0.5,
 threshold = 18, ## in points, roughly 0.25 inches
 panel.args = trellis.panelArgs(),
 ...)
panel.identify.qqmath(x, distribution, groups, subscripts, labels,
 panel.args = trellis.panelArgs(),
 ...)
panel.identify.cloud(x, y, z, subscripts,
 perspective, distance,
 xlim, ylim, zlim,
 screen, R.mat, aspect, scales.3d,
 ...,
 panel.3d.identify,
 n = length(subscripts),
 offset = 0.5,
 threshold = 18,
 labels = subscripts,
 panel.args = trellis.panelArgs())
panel.link.splom(threshold = 18, verbose = getOption("verbose"), ...)
panel.brush.splom(threshold = 18, verbose = getOption("verbose"), ...)

trellis.vpname(name = c("position", "split", "split.location", "toplevel",
 "figure", "panel", "strip", "strip.left",
 "legend", "legend.region", "main", "sub",
 "xlab", "ylab", "xlab.top", "ylab.right", "page"),
 column, row,
 side = c("left", "top", "right", "bottom", "inside"),
 clip.off = FALSE, prefix)
trellis.grobname(name,
 type = c("", "panel", "strip", "strip.left",
 "key", "colorkey"),
 group = 0,
 which.given = lattice.getStatus("current.which.given",
 prefix = prefix),
 which.panel = lattice.getStatus("current.which.panel",
 prefix = prefix),
 column = lattice.getStatus("current.focus.column",
 prefix = prefix),
 row = lattice.getStatus("current.focus.row",
 prefix = prefix),
 prefix = lattice.getStatus("current.prefix"))
trellis.focus(name, column, row, side, clip.off,
 highlight = interactive(), ..., prefix,
 guess = TRUE, verbose = getOption("verbose"))
trellis.switchFocus(name, side, clip.off, highlight, ..., prefix)
trellis.unfocus()
trellis.panelArgs(x, packet.number)

```

### Arguments

|                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Defaults to <code>subscripts</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>distribution, groups</code>                                                      | typical panel arguments of <code>panel.qqmath</code> . These will usually be obtained from <code>panel.args</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>offset</code>                                                                    | the labels are printed either below, above, to the left or to the right of the identified point, depending on the relative location of the mouse click. The <code>offset</code> specifies (in "char" units) how far from the identified point the labels should be printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>threshold</code>                                                                 | threshold in grid's "points" units. Points further than these from the mouse click position are not considered                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>panel.args</code>                                                                | list that contains components names <code>x</code> (and usually <code>y</code> ), to be used if <code>x</code> is missing. Typically, when called after <code>trellis.focus</code> , this would appropriately be the arguments passed to that panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, scales.3d</code> | arguments as passed to <code>panel.cloud</code> . These are required to recompute the relevant three-dimensional projections in <code>panel.identify.cloud</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>panel.3d.identify</code>                                                         | the function that is responsible for the actual interaction once the data rescaling and rotation computations have been done. By default, an internal function similar to <code>panel.identify</code> is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>name</code>                                                                      | A character string indicating which viewport or grob we are looking for. Although these do not necessarily provide access to all viewports and grobs created by a lattice plot, they cover most of the ones that end-users may find interesting. <code>trellis.vpname</code> and <code>trellis.focus</code> deal with viewport names only, and only accept the values explicitly listed above. <code>trellis.grobname</code> is meant to create names for grobs, and can currently accept any value.<br><br>If <code>name</code> , as well as <code>column</code> and <code>row</code> is missing in a call to <code>trellis.focus</code> , the user can click inside a panel (or an associated strip) to focus on that panel. Note however that this assumes equal width and height for each panel, and may not work when this is not true.<br><br>When <code>name</code> is "panel", "strip", or "strip.left", <code>column</code> and <code>row</code> must also be specified. When <code>name</code> is "legend", <code>side</code> must also be specified. |
| <code>column, row</code>                                                               | integers, indicating position of the panel or strip that should be assigned focus in the Trellis layout. Rows are usually calculated from the bottom up, unless the plot was created with <code>as.table=TRUE</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>guess</code>                                                                     | logical. If TRUE, and the display has only one panel, that panel will be automatically selected by a call to <code>trellis.focus</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>side</code>                                                                      | character string, relevant only for legends (i.e., when <code>name="legend"</code> ), indicating their position. Partial specification is allowed, as long as it is unambiguous.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>clip.off</code>                                                                  | logical, whether clipping should be off, relevant when <code>name</code> is "panel" or "strip". This is necessary if axes are to be drawn outside the panel or strip. Note that setting <code>clip.off=FALSE</code> does not necessarily mean that clipping is on; that is determined by conditions in effect during printing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>type</b>                             | A character string specifying whether the grob is specific to a particular panel or strip.<br>When type is "panel", "strip", or "strip.left", information about the panel is added to the grob name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>group</b>                            | An integer specifying whether the grob is specific to a particular group within the plot.<br>When group is greater than zero, information about the group is added to the grob name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>which.given</b> , <b>which.panel</b> | integers, indicating which conditional variable is being represented (within a strip) and the current levels of the conditional variables.<br>When which.panel has length greater than 1, and the type is "strip" or "strip.left", information about the conditional variable is added to the grob name.                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>prefix</b>                           | A character string acting as a prefix identifying the plot of a "trellis" object, primarily used to distinguish otherwise equivalent viewports in different plots. This only becomes relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed, as determined by the prefix argument in <a href="#">print.trellis</a> .<br>Users should not usually need to supply a value for this argument except to interact with an existing plot other than the one plotted last.<br>For switchFocus, ignored except when it does not match the prefix of the currently active plot, in which case an error occurs. |
| <b>highlight</b>                        | logical, whether the viewport being assigned focus should be highlighted. For trellis.focus, the default is TRUE in interactive mode, and trellis.switchFocus by default preserves the setting currently active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>packet.number</b>                    | integer, which panel to get data from. See <a href="#">packet.number</a> for details on how this is calculated                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>verbose</b>                          | whether details will be printed                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>...</b>                              | For panel.identify.qqmath, extra parameters are passed on to panel.identify. For panel.identify, extra arguments are treated as graphical parameters and are used for labelling. For trellis.focus and trellis.switchFocus, these are used (in combination with <a href="#">lattice.options</a> ) for highlighting the chosen viewport if so requested. Graphical parameters can be supplied for panel.link.splom.                                                                                                                                                                                                                                                                        |

## Details

`panel.identify` is similar to [identify](#). When called, it waits for the user to identify points (in the panel being drawn) via mouse clicks. Clicks other than left-clicks terminate the procedure. Although it is possible to call it as part of the panel function, it is more typical to use it to identify points after plotting the whole object, in which case a call to `trellis.focus` first is necessary.

`panel.link.splom` is meant for use with [splom](#), and requires a panel to be chosen using `trellis.focus` before it is called. Clicking on a point causes that and the corresponding projections in other pairwise scatter plots to be highlighted. `panel.brush.splom` is a (misnamed) alias for `panel.link.splom`, retained for back-compatibility.

`panel.identify.qqmath` is a specialized wrapper meant for use with the display produced by [qqmath](#). `panel.identify.qqmath` is a specialized wrapper meant for use with the display produced by [cloud](#). It would be unusual to call them except in a context where default panel function arguments are available through `trellis.panelArgs` (see below).

One way in which `panel.identify` etc. are different from `identify` is in how it uses the `subscripts` argument. In general, when one identifies points in a panel, one wants to identify the origin in the data frame used to produce the plot, and not within that particular panel. This information is available to the `panel` function, but only in certain situations. One way to ensure that `subscripts` is available is to specify `subscripts = TRUE` in the high level call such as `xyplot`. If `subscripts` is not explicitly specified in the call to `panel.identify`, but is available in `panel.args`, then those values will be used. Otherwise, they default to `seq_along(x)`. In either case, the final return value will be the `subscripts` that were marked.

The process of printing (plotting) a Trellis object builds up a grid layout with named viewports which can then be accessed to modify the plot further. While full flexibility can only be obtained by using grid functions directly, a few lattice functions are available for the more common tasks.

`trellis.focus` can be used to move to a particular panel or strip, identified by its position in the array of panels. It can also be used to focus on the viewport corresponding to one of the labels or a legend, though such usage would be less useful. The exact viewport is determined by the name along with the other arguments, not all of which are relevant for all names. Note that when more than one object is plotted on a page, `trellis.focus` will always go to the plot that was created last. For more flexibility, use grid functions directly (see note below).

After a successful call to `trellis.focus`, the desired viewport (typically panel or strip area) will be made the ‘current’ viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a “trellis” object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which packet belongs in which position in this layout) is retained for the last “trellis” object plotted, and is available through `trellis.currentLayout`.

`trellis.unfocus` unsets the focus, and makes the top level viewport the current viewport.

`trellis.switchFocus` is a convenience function to switch from one viewport to another, while preserving the current row and column. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, `trellis.panelArgs` can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

```
trellis.panelArgs()
```

This usage is also allowed when a “trellis” object is being printed, e.g. inside the panel functions or the axis function (but not inside the `prepanel` function). `trellis.panelArgs` can also retrieve the panel arguments from any “trellis” object. Note that for this usage, one needs to specify the `packet.number` (as described under the `panel` entry in `xyplot`) and not the position in the layout, because a layout determines the panel only **after** the object has been printed.

It is usually not necessary to call `trellis.vpname` and `trellis.groiname` directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

## Value

`panel.identify` returns an integer vector containing the `subscripts` of the identified points (see details above). The equivalent of `identify` with `pos=TRUE` is not yet implemented, but can be considered for addition if requested.

`trellis.panelArgs` returns a named list of arguments that were available to the panel function for the chosen panel.

`trellis.vpname` and `trellis.grobnane` return character strings.

`trellis.focus` has a meaningful return value only if it has been used to focus on a panel interactively, in which case the return value is a list with components `col` and `row` giving the column and row positions respectively of the chosen panel, unless the choice was cancelled (by a right click), in which case the return value is `NULL`. If click was outside a panel, both `col` and `row` are set to 0.

### Note

The viewports created by lattice are accessible to the user through `trellis.focus` as described above. Functions from the grid package can also be used directly. For example, `current.vpTree` can be used to inspect the current viewport tree and `seekViewport` or `downViewport` can be used to navigate to these viewports. For such usage, `trellis.vpname` and `trellis.grobnane` provides a portable way to access the appropriate viewports and grobs by name.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>. Felix Andrews provided initial implementations of `panel.identify.qqmath` and support for focusing on panels interactively.

### Examples

```
Not run:
xyplot(1:10 ~ 1:10)
trellis.focus("panel", 1, 1)
panel.identify()

End(Not run)

xyplot(Petal.Length ~ Sepal.Length | Species, iris, layout = c(2, 2))
Sys.sleep(1)

trellis.focus("panel", 1, 1)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

trellis.focus("panel", 2, 1)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

trellis.focus("panel", 1, 2)
do.call("panel.lmline", trellis.panelArgs())
Sys.sleep(0.5)
trellis.unfocus()

choosing loess smoothing parameter
```

```

p <- xyplot(dist ~ speed, cars)

panel.loessresid <-
 function(x = panel.args$x,
 y = panel.args$y,
 span,
 panel.args = trellis.panelArgs())
{
 fm <- loess(y ~ x, span = span)
 xgrid <- do.breaks(current.panel.limits()$xlim, 50)
 ygrid <- predict(fm, newdata = data.frame(x = xgrid))
 panel.lines(xgrid, ygrid)
 pred <- predict(fm)
 ## center residuals so that they fall inside panel
 resids <- y - pred + mean(y)
 fm.resid <- loess.smooth(x, resids, span = span)
 ##panel.points(x, resids, col = 1, pch = 4)
 panel.lines(fm.resid, col = 1)
}

spans <- c(0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8)
update(p, index.cond = list(rep(1, length(spans))))
panel.locs <- trellis.currentLayout()

i <- 1

for (row in 1:nrow(panel.locs))
 for (column in 1:ncol(panel.locs))
 if (panel.locs[row, column] > 0)
 {
 trellis.focus("panel", row = row, column = column,
 highlight = FALSE)
 panel.loessresid(span = spans[i])
 grid::grid.text(paste("span = ", spans[i]),
 x = 0.25,
 y = 0.75,
 default.units = "npc")
 trellis.unfocus()
 i <- i + 1
 }
}

```

## Description

Default panel function for barchart.

## Usage

```
panel.barchart(x, y, box.ratio = 1, box.width,
```

```

horizontal = TRUE,
origin = NULL, reference = TRUE,
stack = FALSE,
groups = NULL,
col = if (is.null(groups)) plot.polygon$col
 else superpose.polygon$col,
border = if (is.null(groups)) plot.polygon$border
 else superpose.polygon$border,
lty = if (is.null(groups)) plot.polygon$lty
 else superpose.polygon$lty,
lwd = if (is.null(groups)) plot.polygon$lwd
 else superpose.polygon$lwd,
..., identifier = "barchart")

```

### Arguments

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                     | Extent of Bars. By default, bars start at left of panel, unless <code>origin</code> is specified, in which case they start there.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>y</code>                     | Horizontal location of bars. Possibly a factor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>box.ratio</code>             | Ratio of bar width to inter-bar space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>box.width</code>             | Thickness of bars in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.                                                                                                                                                                                                                                                                                                      |
| <code>horizontal</code>            | Logical flag. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation.                                                                                                                                                                                                                                             |
| <code>origin</code>                | The origin for the bars. For grouped displays with <code>stack = TRUE</code> , this argument is ignored and the origin set to 0. Otherwise, defaults to NULL, in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, <code>origin = 0</code> is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative). |
| <code>reference</code>             | Logical, whether a reference line is to be drawn at the origin.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>stack</code>                 | logical, relevant when <code>groups</code> is non-null. If FALSE (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.                                                                                                                                                                                                                                                                                                                                                        |
| <code>groups</code>                | Optional grouping variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>col, border, lty, lwd</code> | Graphical parameters for the bars. By default, the trellis parameter <code>plot.polygon</code> is used if there is no grouping variable, otherwise <code>superpose.polygon</code> is used. <code>col</code> gives the fill color, <code>border</code> the border color, and <code>lty</code> and <code>lwd</code> the line type and width of the borders.                                                                                                                                                                                     |
| <code>...</code>                   | Extra arguments will be accepted but ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>identifier</code>            | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level `barchart` call directly.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

[barchart](#)

**Examples**

```
barchart(yield ~ variety | site, data = barley,
 groups = year, layout = c(1,6), origin = 0,
 ylab = "Barley Yield (bushels/acre)",
 scales = list(x = list(abbreviate = TRUE,
 minlength = 5)))
```

F\_1\_panel.bwplot

*Default Panel Function for bwplot*

**Description**

This is the default panel function for `bwplot`.

**Usage**

```
panel.bwplot(x, y, box.ratio = 1,
 box.width = box.ratio / (1 + box.ratio),
 horizontal = TRUE,
 pch, col, alpha, cex,
 font, fontfamily, fontface,
 fill, varwidth = FALSE,
 notch = FALSE, notch.frac = 0.5,
 ...,
 levels.fos,
 stats = boxplot.stats,
 coef = 1.5,
 do.out = TRUE,
 identifier = "bwplot")
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>       | numeric vector or factor. Boxplots drawn for each unique value of <code>y</code> ( <code>x</code> ) if <code>horizontal</code> is TRUE (FALSE)                                                                                                                                                  |
| <code>box.ratio</code>  | ratio of box thickness to inter box space                                                                                                                                                                                                                                                       |
| <code>box.width</code>  | thickness of box in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.                                                         |
| <code>horizontal</code> | logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation. |

|                                                  |                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pch, col, alpha, cex, font, fontfamily, fontface | graphical parameters controlling the dot. pch=" " is treated specially, by replacing the dot with a line (similar to <a href="#">boxplot</a> )                                                                                                                                                                                                          |
| fill                                             | color to fill the boxplot                                                                                                                                                                                                                                                                                                                               |
| varwidth                                         | logical. If TRUE, widths of boxplots are proportional to the number of points used in creating it.                                                                                                                                                                                                                                                      |
| notch                                            | if notch is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is ‘strong evidence’ that the two medians differ (Chambers et al., 1983, p. 62). See <a href="#">boxplot.stats</a> for the calculations used.                                                                                             |
| notch.frac                                       | numeric in (0,1). When notch=TRUE, the fraction of the box width that the notches should use.                                                                                                                                                                                                                                                           |
| stats                                            | a function, defaulting to <a href="#">boxplot.stats</a> , that accepts a numeric vector and returns a list similar to the return value of <a href="#">boxplot.stats</a> . The function must accept arguments coef and do.out even if they do not use them (a ... argument is good enough). This function is used to determine the box and whisker plot. |
| coef, do.out                                     | passed to stats                                                                                                                                                                                                                                                                                                                                         |
| levels.fos                                       | numeric values corresponding to positions of the factor or shingle variable. For internal use.                                                                                                                                                                                                                                                          |
| ...                                              | further arguments, ignored.                                                                                                                                                                                                                                                                                                                             |
| identifier                                       | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                     |

## Details

Creates Box and Whisker plot of x for every level of y (or the other way round if horizontal=FALSE). By default, the actual boxplot statistics are calculated using [boxplot.stats](#). Note that most arguments controlling the display can be supplied to the high-level [bwplot](#) call directly.

Although the graphical parameters for the dot representing the median can be controlled by optional arguments, many others can not. These parameters are obtained from the relevant settings parameters ("box.rectangle" for the box, "box.umbrella" for the whiskers and "plot.symbol" for the outliers).

## Examples

```
bwplot(voice.part ~ height, data = singer,
 xlab = "Height (inches)",
 panel = function(...) {
 panel.grid(v = -1, h = 0)
 panel.bwplot(...)
 },
 par.settings = list(plot.symbol = list(pch = 4)))
```

```
bwplot(voice.part ~ height, data = singer,
 xlab = "Height (inches)",
 notch = TRUE, pch = "|")
```

F\_1\_panel.cloud      *Default Panel Function for cloud*

### Description

These are default panel functions controlling `cloud` and `wireframe` displays.

### Usage

```
panel.cloud(x, y, subscripts, z,
 groups = NULL,
 perspective = TRUE,
 distance = if (perspective) 0.2 else 0,
 xlim, ylim, zlim,
 panel.3d.cloud = "panel.3dscatter",
 panel.3d.wireframe = "panel.3dwire",
 screen = list(z = 40, x = -60),
 R.mat = diag(4), aspect = c(1, 1),
 par.box = NULL,
 xlab, ylab, zlab,
 xlab.default, ylab.default, zlab.default,
 scales.3d,
 proportion = 0.6,
 wireframe = FALSE,
 scpos,
 ...,
 at,
 identifier = "cloud")
panel.wireframe(...)
panel.3dscatter(x, y, z, rot.mat, distance,
 groups, type = "p",
 xlim, ylim, zlim,
 xlim.scaled, ylim.scaled, zlim.scaled,
 zero.scaled,
 col, col.point, col.line,
 lty, lwd, cex, pch,
 cross, ..., .scale = FALSE, subscripts,
 identifier = "3dscatter")
panel.3dwire(x, y, z, rot.mat = diag(4), distance,
 shade = FALSE,
 shade.colors.palette = trellis.par.get("shade.colors")$palette,
 light.source = c(0, 0, 1000),
 xlim, ylim, zlim,
 xlim.scaled,
```

```

ylim.scaled,
zlim.scaled,
col = if (shade) "transparent" else "black",
lty = 1, lwd = 1,
alpha,
col.groups = superpose.polygon$col,
polynum = 100,
...,
.scale = FALSE,
drape = FALSE,
at,
col.regions = regions$col,
alpha.regions = regions$alpha,
identifier = "3dwire")

```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x, y, z</b>     | numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For <code>panel.cloud</code> these are essentially the same as the data passed to the high level plot (except if <code>formula</code> was a matrix, the appropriate <code>x</code> and <code>y</code> vectors are generated). By the time they are passed to <code>panel.3dscatter</code> and <code>panel.3dwire</code> , they have been appropriately subsetted (using subscripts) and scaled (to lie inside a bounding box, usually the [-0.5, 0.5] cube). Further, for <code>panel.3dwire</code> , <code>x</code> and <code>y</code> are shorter than <code>z</code> and represent the sorted locations defining a rectangular grid. Also in this case, <code>z</code> may be a matrix if the display is grouped, with each column representing one surface. |
| <b>subscripts</b>  | index specifying which points to draw. The same <code>x</code> , <code>y</code> and <code>z</code> values (representing the whole data) are passed to <code>panel.cloud</code> for each panel. <code>subscripts</code> specifies the subset of rows to be used for the particular panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>groups</b>      | specification of a grouping variable, passed down from the high level functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>perspective</b> | logical, whether to plot a perspective view. Setting this to FALSE is equivalent to setting <code>distance</code> to 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>distance</b>    | numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is 1 / <code>distance</code> . This is described in a little more detail in the documentation for <code>cloud</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>screen</b>      | A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive <code>z</code> -axis, and the <code>x</code> and <code>y</code> axes in the usual position. Each component of the list should be named one of " <code>x</code> ", " <code>y</code> " or " <code>z</code> " (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>R.mat</b>       | initial rotation matrix in homogeneous coordinates, to be applied to the data before <code>screen</code> rotates the view further.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>par.box</b>     | graphical parameters for box, namely, <code>col</code> , <code>lty</code> and <code>lwd</code> . By default obtained from the parameter <code>box.3d</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <code>xlim, ylim, zlim</code>                      | limits for the respective axes. As with other lattice functions, these could each be a numeric 2-vector or a character vector indicating levels of a factor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>panel.3d.cloud, panel.3d.wireframe</code>    | functions that draw the data-driven part of the plot (as opposed to the bounding box and scales) in <code>cloud</code> and <code>wireframe</code> . This function is called after the ‘back’ of the bounding box is drawn, but before the ‘front’ is drawn.<br>Any user-defined custom display would probably want to change these functions. The intention is to pass as much information to this function as might be useful (not all of which are used by the defaults). In particular, these functions can expect arguments called <code>xlim</code> , <code>ylim</code> , <code>zlim</code> which give the bounding box ranges in the original data scale and <code>xlim.scaled</code> , <code>ylim.scaled</code> , <code>zlim.scaled</code> which give the bounding box ranges in the transformed scale. More arguments can be considered on request. |
| <code>aspect</code>                                | aspect as in <code>cloud</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>xlab, ylab, zlab</code>                      | Labels, have to be lists. Typically the user will not manipulate these, but instead control this via arguments to <code>cloud</code> directly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <code>scales.3d</code>                             | list defining the scales                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>proportion</code>                            | numeric scalar, gives the length of arrows as a proportion of the sides                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>scpos</code>                                 | A list with three components <code>x</code> , <code>y</code> and <code>z</code> (each a scalar integer), describing which of the 12 sides of the cube the scales should be drawn. The defaults should be OK. Valid values are <code>x</code> : 1, 3, 9, 11; <code>y</code> : 8, 5, 7, 6 and <code>z</code> : 4, 2, 10, 12. (See comments in the source code of <code>panel.cloud</code> to see the details of this enumeration.)                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>wireframe</code>                             | logical, indicating whether this is a wireframe plot                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>drape</code>                                 | logical, whether the facets will be colored by height, in a manner similar to <code>levelplot</code> . This is ignored if <code>shade=TRUE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>at, col.regions, alpha.regions</code>        | deals with specification of colors when <code>drape = TRUE</code> in <code>wireframe</code> . <code>at</code> can be a numeric vector, <code>col.regions</code> a vector of colors, and <code>alpha.regions</code> a numeric scalar controlling transparency. The resulting behaviour is similar to <code>levelplot</code> , <code>at</code> giving the breakpoints along the <code>z</code> -axis where colors change, and the other two determining the colors of the facets that fall in between.                                                                                                                                                                                                                                                                                                                                                        |
| <code>rot.mat</code>                               | 4x4 transformation matrix in homogeneous coordinates. This gives the rotation matrix combining the screen and <code>R.mat</code> arguments to <code>panel.cloud</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>type</code>                                  | Character vector, specifying type of cloud plot. Can include one or more of “ <code>p</code> ”, “ <code>l</code> ”, “ <code>h</code> ” or “ <code>b</code> ”. “ <code>p</code> ” and “ <code>l</code> ” mean ‘points’ and ‘lines’ respectively, and “ <code>b</code> ” means ‘both’. “ <code>h</code> ” stands for ‘histogram’, and causes a line to be drawn from each point to the X-Y plane (i.e., the plane representing $z = 0$ ), or the lower (or upper) bounding box face, whichever is closer.                                                                                                                                                                                                                                                                                                                                                     |
| <code>xlim.scaled, ylim.scaled, zlim.scaled</code> | axis limits (after being scaled to the bounding box)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>zero.scaled</code>                           | z-axis location (after being scaled to the bounding box) of the X-Y plane in the original data scale, to which lines will be dropped (if within range) from each point when <code>type = "h"</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cross</code>                                               | logical, defaults to TRUE if <code>pch = "+"</code> . <code>panel.3dscatter</code> can represent each point by a 3d ‘cross’ of sorts (it’s much easier to understand looking at an example than from a description). This is different from the usual <code>pch</code> argument, and reflects the depth of the points and the orientation of the axes. This argument indicates whether this feature will be used.<br>This is useful for two reasons. It can be set to FALSE to use “+” as the plotting character in the regular sense. It can also be used to force this feature in grouped displays.                                                                                                                                     |
| <code>shade</code>                                               | logical, indicating whether the surface is to be colored using an illumination model with a single light source                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>shade.colors.palette</code>                                | a function (or the name of one) that is supposed to calculate the color of a facet when shading is being used. Three pieces of information are available to the function: first, the cosine of the angle between the incident light ray and the normal to the surface (representing foreshortening); second, the cosine of half the angle between the reflected ray and the viewing direction (useful for non-Lambertian surfaces); and third, the scaled (average) height of that particular facet with respect to the total plot z-axis limits.<br>All three numbers should be between 0 and 1. The <code>shade.colors.palette</code> function should return a valid color. The default function is obtained from the trellis settings. |
| <code>light.source</code>                                        | a 3-vector representing (in cartesian coordinates) the light source. This is relative to the viewing point being (0, 0, 1/distance) (along the positive z-axis), keeping in mind that all observations are bounded within the [-0.5, 0.5] cube                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>polynum</code>                                             | quadrilateral faces are drawn in batches of <code>polynum</code> at a time. Drawing too few at a time increases the total number of calls to the underlying <code>grid.polygon</code> function, which affects speed. Trying to draw too many at once may be unnecessarily memory intensive. This argument controls the trade-off.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>col.groups</code>                                          | colors for different groups                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>col, col.point, col.line, lty, lwd, cex, pch, alpha</code> | Graphical parameters. Some other arguments (such as <code>lwd</code> for line width) may also be passed through the ... argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>                                                 | other parameters, passed down when appropriate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>.scale</code>                                              | Logical flag, indicating whether <code>x</code> , <code>y</code> , and <code>z</code> should be assumed to be in the original data scale and hence scaled before being plotted. <code>x</code> , <code>y</code> , and <code>z</code> are usually already scaled. However, setting <code>.scale=TRUE</code> may be helpful for calls to <code>panel.3dscatter</code> and <code>panel.3dwire</code> in user-supplied panel functions.                                                                                                                                                                                                                                                                                                       |
| <code>identifier</code>                                          | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Details

These functions together are responsible for the content drawn inside each panel in `cloud` and `wireframe`. `panel.wireframe` is a wrapper to `panel.cloud`, which does the actual work.

`panel.cloud` is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether `wireframe` is TRUE, it calls either `panel.3d.wireframe` or `panel.3d.cloud`, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For `cloud`, the data is unstructured, and `x`, `y` and `z` are all passed to the `panel.3d.cloud`

function. For wireframe, on the other hand, *x* and *y* are increasing vectors with unique values, defining a rectangular grid. *z* must be a matrix with `length(x) * length(y)` rows, and as many columns as the number of groups.

`panel.3dscatter` is the default `panel.3d.cloud` function. It has a type argument similar to `panel.xyplot`, and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)

`panel.3dwire` is the default `panel.3d.wireframe` function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about `polynom` facets, and draws them all at once. This avoids the overhead of drawing `grid.polygon` repeatedly, speeding up the rendering considerably. If `shade = TRUE`, these attempt to color the surface as being illuminated from a light source at `light.source`. `palette.shade` is a simple function that provides the deafult shading colors

Multiple surfaces are drawn if `groups` is non-null in the call to `wireframe`, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

F\_1\_panel.densityplot *Default Panel Function for densityplot*

## Description

This is the default panel function for `densityplot`.

## Usage

```
panel.densityplot(x, darg, plot.points = "jitter", ref = FALSE,
 groups = NULL, weights = NULL,
 jitter.amount, type, ...,
 identifier = "density")
```

## Arguments

- |                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code><br><code>darg</code><br><code>plot.points</code> | data points for which density is to be estimated<br>list of arguments to be passed to the <code>density</code> function. Typically, this should be a list with zero or more of the following components : <code>bw</code> , <code>adjust</code> , <code>kernel</code> , <code>window</code> , <code>width</code> , <code>give.Rkern</code> , <code>n</code> , <code>from</code> , <code>to</code> , <code>cut</code> , <code>na.rm</code> (see <code>density</code> for details)<br>logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are "rug", in which case <code>panel.rug</code> is used to plot a 'rug', and "jitter", in which case the points are jittered vertically to better distinguish overlapping points. |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                            |                                                                                                                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ref</code>           | logical, whether to draw x-axis                                                                                                                                                                     |
| <code>groups</code>        | an optional grouping variable. If present, <code>panel.superpose</code> will be used instead to display each subgroup                                                                               |
| <code>weights</code>       | numeric vector of weights for the density calculations. If this is specified, the ... part must also include a <code>subscripts</code> argument that matches the weights to <code>x</code> .        |
| <code>jitter.amount</code> | when <code>plot.points="jitter"</code> , the value to use as the <code>amount</code> argument to <code>jitter</code> .                                                                              |
| <code>type</code>          | type argument used to plot points, if requested. This is not expected to be useful, it is available mostly to protect a <code>type</code> argument, if specified, from affecting the density curve. |
| <code>...</code>           | extra graphical parameters. Note that additional arguments to <code>panel.rug</code> cannot be passed on through <code>panel.densityplot</code> .                                                   |
| <code>identifier</code>    | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                 |

*F\_1\_panel.dotplot*

*Default Panel Function for dotplot*

**Description**

Default panel function for `dotplot`.

**Usage**

```
panel.dotplot(x, y, horizontal = TRUE,
 pch, col, lty, lwd,
 col.line, levels.fos,
 groups = NULL,
 ...,
 identifier = "dotplot")
```

**Arguments**

|                                           |                                                                                                                                                                                                                                                                                              |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x,y</code>                          | variables to be plotted in the panel. Typically <code>y</code> is the ‘factor’                                                                                                                                                                                                               |
| <code>horizontal</code>                   | logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation. |
| <code>pch, col, lty, lwd, col.line</code> | graphical parameters                                                                                                                                                                                                                                                                         |
| <code>levels.fos</code>                   | locations where reference lines will be drawn                                                                                                                                                                                                                                                |

|            |                                                                                                                                                                                       |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| groups     | grouping variable (affects graphical parameters)                                                                                                                                      |
| ...        | extra parameters, passed to <code>panel.xyplot</code> which is responsible for drawing the foreground points ( <code>panel.dotplot</code> only draws the background reference lines). |
| identifier | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                   |

## Details

Creates (possibly grouped) Dotplot of x against y or vice versa

`F_1_panel.histogram`      *Default Panel Function for histogram*

## Description

This is the default panel function for `histogram`.

## Usage

```
panel.histogram(x,
 breaks,
 equal.widths = TRUE,
 type = "density",
 nint = round(log2(length(x)) + 1),
 alpha, col, border, lty, lwd,
 ...,
 identifier = "histogram")
```

## Arguments

|                              |                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| x                            | The data points for which the histogram is to be drawn                                              |
| breaks                       | The breakpoints for the histogram                                                                   |
| equal.widths                 | logical used when <code>breaks==NULL</code>                                                         |
| type                         | Type of histogram, possible values being "percent", "density" and "count"                           |
| nint                         | Number of bins for the histogram                                                                    |
| alpha, col, border, lty, lwd | graphical parameters for bars; defaults are obtained from the <code>plot.polygon</code> settings.   |
| ...                          | other arguments, passed to <code>hist</code> when deemed appropriate                                |
| identifier                   | A character string that is prepended to the names of grobs that are created by this panel function. |

*F\_1\_panel.levelplot*      *Panel Functions for levelplot and contourplot*

---

**Description**

These are the default panel functions for [levelplot](#) and [contourplot](#). Also documented is an alternative raster-based panel function for use with [levelplot](#).

**Usage**

```
panel.levelplot(x, y, z,
 subscripts,
 at = pretty(z),
 shrink,
 labels,
 label.style = c("mixed", "flat", "align"),
 contour = FALSE,
 region = TRUE,
 col = add.line$col,
 lty = add.line$lty,
 lwd = add.line$lwd,
 border = "transparent",
 border.lty = 1,
 border.lwd = 0.1,
 ...,
 col.regions = regions$col,
 alpha.regions = regions$alpha,
 identifier = "levelplot")
panel.contourplot(...)

panel.levelplot.raster(x, y, z,
 subscripts,
 at = pretty(z),
 ...,
 col.regions = regions$col,
 alpha.regions = regions$alpha,
 interpolate = FALSE,
 identifier = "levelplot")
```

### Arguments

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y, z</code>                | Variables defining the plot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>subscripts</code>             | Integer vector indicating what subset of <code>x, y</code> and <code>z</code> to draw.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>at</code>                     | Numeric vector giving breakpoints along the range of <code>z</code> . See <a href="#">levelplot</a> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>shrink</code>                 | Either a numeric vector of length 2 (meant to work as both <code>x</code> and <code>y</code> components), or a list with components <code>x</code> and <code>y</code> which are numeric vectors of length 2. This allows the rectangles to be scaled proportional to the <code>z</code> -value. The specification can be made separately for widths ( <code>x</code> ) and heights ( <code>y</code> ). The elements of the length 2 numeric vector gives the minimum and maximum proportion of shrinkage (corresponding to min and max of <code>z</code> ). |
| <code>labels</code>                 | Either a logical scalar indicating whether the labels are to be drawn, or a character or expression vector giving the labels associated with the <code>at</code> values. Alternatively, <code>labels</code> can be a list with the following components:                                                                                                                                                                                                                                                                                                    |
|                                     | <code>labels</code> : a character or expression vector giving the labels. This can be omitted, in which case the defaults will be used.                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                                     | <code>col, cex, alpha</code> : graphical parameters for label texts                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                                     | <code>fontfamily, fontface, font</code> : font used for the labels                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>label.style</code>            | Controls how label positions and rotation are determined. A value of "flat" causes the label to be positioned where the contour is flattest, and the label is not rotated. A value of "align" causes the label to be drawn as far from the boundaries as possible, and the label is rotated to align with the contour at that point. The default is to mix these approaches, preferring the flattest location unless it is too close to the boundaries.                                                                                                     |
| <code>contour</code>                | A logical flag, specifying whether contour lines should be drawn.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>region</code>                 | A logical flag, specifying whether inter-contour regions should be filled with appropriately colored rectangles.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>col, lty, lwd</code>          | Graphical parameters for contour lines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>border</code>                 | Border color for rectangles used when <code>region=TRUE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>border.lty, border.lwd</code> | Graphical parameters for the border                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>                    | Extra parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>col.regions</code>            | A vector of colors, or a function to produce a vector of colors, to be used if <code>region=TRUE</code> . Each interval defined by <code>at</code> is assigned a color, so the number of colors actually used is one less than the length of <code>at</code> . See <a href="#">level.colors</a> for details on how the color assignment is done.                                                                                                                                                                                                            |
| <code>alpha.regions</code>          | numeric scalar controlling transparency of facets                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>interpolate</code>            | logical, passed to <a href="#">grid.raster</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>identifier</code>             | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Details

The same panel function is used for both `levelplot` and `contourplot` (which differ only in default values of some arguments). `panel.contourplot` is a simple wrapper to `panel.levelplot`.

When `contour=TRUE`, the `contourLines` function is used to calculate the contour lines.

`panel.levelplot.raster` is an alternative panel function that uses the raster drawing abilities in R 2.11.0 and higher (through `grid.raster`). It has fewer options (e.g., can only render data on an equispaced grid), but can be more efficient. When using `panel.levelplot.raster`, it may be desirable to render the color key in the same way. This is possible, but must be done separately; see `levelplot` for details.

### See Also

`levelplot, level.colors, contourLines`

### Examples

```
require(grid)

levelplot(rnorm(10) ~ 1:10 + sort(runif(10)), panel = panel.levelplot)

suppressWarnings(plot(levelplot(rnorm(10) ~ 1:10 + sort(runif(10)),
 panel = panel.levelplot.raster,
 interpolate = TRUE)))

levelplot(volcano, panel = panel.levelplot.raster)

levelplot(volcano, panel = panel.levelplot.raster,
 col.regions = topo.colors, cuts = 30, interpolate = TRUE)
```

### Description

This is the default superpanel function for `splom`.

### Usage

```
panel.pairs(z,
 panel = latticegetOption("panel.splom"),
 lower.panel = panel,
 upper.panel = panel,
 diag.panel = "diag.panel.splom",
 as.matrix = FALSE,
 groups = NULL,
 panel.subscripts,
 subscripts,
 pscales = 5,
 prepanel.limits = scale.limits,
 varnames = colnames(z),
 varname.col, varname.cex, varname.font,
 varname.fontfamily, varname.fontface,
```

```

axis.text.col, axis.text.cex, axis.text.font,
axis.text.fontfamily, axis.text.fontface,
axis.text.lineheight,
axis.line.col, axis.line.lty, axis.line.lwd,
axis.line.alpha, axis.line.tck,
...)
diag.panel.splom(x = NULL,
 varname = NULL, limits, at = NULL, labels = NULL,
 draw = TRUE, tick.number = 5,
 varname.col, varname.cex,
 varname.lineheight, varname.font,
 varname.fontfamily, varname.fontface,
 axis.text.col, axis.text.alpha,
 axis.text.cex, axis.text.font,
 axis.text.fontfamily, axis.text.fontface,
 axis.text.lineheight,
 axis.line.col, axis.line.alpha,
 axis.line.lty, axis.line.lwd,
 axis.line.tck,
 ...)

```

## Arguments

|                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>z</code>                               | The data frame used for the plot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>panel, lower.panel, upper.panel</code> | The panel function used to display each pair of variables. If specified, <code>lower.panel</code> and <code>upper.panel</code> are used for panels below and above the diagonal respectively.<br>In addition to extra arguments not recognized by <code>panel.pairs</code> , the list of arguments passed to the panel function also includes arguments named <code>i</code> and <code>j</code> , with values indicating the row and column of the scatterplot matrix being plotted.                                                                                                                                                                  |
| <code>diag.panel</code>                      | The panel function used for the diagonals. See arguments to <code>diag.panel.splom</code> to know what arguments this function is passed when called.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>as.matrix</code>                       | logical. If <code>TRUE</code> , the layout of the panels will have origin on the top left instead of bottom left (similar to <code>pairs</code> ). This is in essence the same functionality as provided by <code>as.table</code> for the panel layout                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>groups</code>                          | Grouping variable, if any                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>panel.subscripts</code>                | logical specifying whether the panel function accepts an argument named <code>subscripts</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>subscripts</code>                      | The indices of the rows of <code>z</code> that are to be displayed in this (super)panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>pscales</code>                         | Controls axis labels, passed down from <code>splom</code> . If <code>pscales</code> is a single number, it indicates the approximate number of equally-spaced ticks that should appear on each axis. If <code>pscales</code> is a list, it should have one component for each column in <code>z</code> , each of which itself a list with the following valid components:<br><code>at</code> : a numeric vector specifying tick locations<br><code>labels</code> : character vector labels to go with <code>at</code><br><code>limits</code> : numeric 2-vector specifying axis limits (should be made more flexible at some point to handle factors) |

These are specifications on a per-variable basis, and used on all four sides in the diagonal cells used for labelling. Factor variables are labelled with the factor names. Use `pscales=0` to suppress the axes entirely.

`prepanel.limits`

A function to calculate suitable axis limits given a single argument `x` containing a data vector. The return value of the function should be similar to the `xlim` or `ylim` argument documented in [xyplot](#); that is, it should be a numeric or `DateTime` vector of length 2 defining a range, or a character vector representing levels of a factor.

Most high-level lattice plots (such as `xyplot`) use the `prepanel` function for deciding on axis limits from data. This function serves a similar function by calculating the per-variable limits. These limits can be overridden by the corresponding `limits` component in the `pscales` list.

|                                                                       |                                                                                                                                                                                                                             |
|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                                                        | data vector corresponding to that row / column (which will be the same for diagonal ‘panels’).                                                                                                                              |
| <code>varname</code>                                                  | (scalar) character string or expression that is to be written centred within the panel                                                                                                                                      |
| <code>limits</code>                                                   | numeric of length 2, or, vector of characters, specifying the scale for that panel (used to calculate tick locations when missing)                                                                                          |
| <code>at</code>                                                       | locations of tick marks                                                                                                                                                                                                     |
| <code>labels</code>                                                   | optional labels for tick marks                                                                                                                                                                                              |
| <code>draw</code>                                                     | A logical flag specifying whether to draw the tick marks and labels. If <code>FALSE</code> , variable names are shown but axis annotation is omitted.                                                                       |
| <code>tick.number</code>                                              | A Numeric scalar giving the suggested number of tick marks.                                                                                                                                                                 |
| <code>varnames</code>                                                 | A character or expression vector or giving names to be used for the variables in <code>x</code> . By default, the column names of <code>x</code> .                                                                          |
| <code>varname.col</code>                                              | Color for the variable name in each diagonal panel. See <a href="#">gpar</a> for details on this and the other graphical parameters listed below.                                                                           |
| <code>varname.cex</code>                                              | Size multiplier for the variable name in each diagonal panel.                                                                                                                                                               |
| <code>varname.lineheight</code>                                       | Line height for the variable name in each diagonal panel.                                                                                                                                                                   |
| <code>varname.font, varname.fontfamily, varname.fontface</code>       | Font specification for the variable name in each diagonal panel.                                                                                                                                                            |
| <code>axis.text.col</code>                                            | Color for axis label text.                                                                                                                                                                                                  |
| <code>axis.text.cex</code>                                            | Size multiplier for axis label text.                                                                                                                                                                                        |
| <code>axis.text.font, axis.text.fontfamily, axis.text.fontface</code> | Font specification for axis label text.                                                                                                                                                                                     |
| <code>axis.text.lineheight</code>                                     | Line height for axis label text.                                                                                                                                                                                            |
| <code>axis.text.alpha</code>                                          | Alpha-transparency for axis label text.                                                                                                                                                                                     |
| <code>axis.line.col</code>                                            | Color for the axes.                                                                                                                                                                                                         |
| <code>axis.line.lty</code>                                            | Line type for the axes.                                                                                                                                                                                                     |
| <code>axis.line.lwd</code>                                            | Line width for the axes.                                                                                                                                                                                                    |
| <code>axis.line.alpha</code>                                          | Alpha-transparency for the axes.                                                                                                                                                                                            |
| <code>axis.line.tck</code>                                            | A numeric multiplier for the length of tick marks in diagonal panels.                                                                                                                                                       |
| <code>...</code>                                                      | Further arguments, passed on to <code>panel</code> , <code>lower.panel</code> , <code>upper.panel</code> , and <code>diag.panel</code> from <code>panel.pairs</code> . Currently ignored by <code>diag.panel.splom</code> . |

## Details

`panel.pairs` is the function that is actually used as the panel function in a "trellis" object produced by `splom`.

## Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

## See Also

[splom](#)

## Examples

```
Cmat <- outer(1:6,1:6,
 function(i,j) rainbow(11, start=.12, end=.5)[i+j-1])

splom(~diag(6), as.matrix = TRUE,
 panel = function(x, y, i, j, ...) {
 panel.fill(Cmat[i,j])
 panel.text(.5,.5, paste("(",i,",",j,")",sep=""))
 })
```

F\_1\_panel.parallel      *Default Panel Function for parallel*

## Description

This is the default panel function for `parallel`.

## Usage

```
panel.parallel(x, y, z, subscripts,
 groups = NULL,
 col, lwd, lty, alpha,
 common.scale = FALSE,
 lower,
 upper,
 ...,
 horizontal.axis = TRUE,
 identifier = "parallel")
```

## Arguments

|                         |                                                                                                                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>       | dummy variables, ignored.                                                                                                                                                                   |
| <code>z</code>          | The data frame used for the plot. Each column will be coerced to numeric before being plotted, and an error will be issued if this fails.                                                   |
| <code>subscripts</code> | The indices of the rows of <code>z</code> that are to be displayed in this panel.                                                                                                           |
| <code>groups</code>     | An optional grouping variable. If specified, different groups are distinguished by use of different graphical parameters (i.e., rows of <code>z</code> in the same group share parameters). |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>col, lwd, lty, alpha</code> | graphical parameters (defaults to the settings for <code>superpose.line</code> ). If <code>groups</code> is non-null, these parameters used one for each group. Otherwise, they are recycled and used to distinguish between rows of the data frame <code>z</code> .                                                                                                            |
| <code>common.scale</code>         | logical, whether a common scale should be used columns of <code>z</code> . Defaults to <code>FALSE</code> , in which case the horizontal range for each column is different (as determined by <code>lower</code> and <code>upper</code> ).                                                                                                                                      |
| <code>lower, upper</code>         | numeric vectors replicated to be as long as the number of columns in <code>z</code> . Determines the lower and upper bounds to be used for scaling the corresponding columns of <code>z</code> after coercing them to numeric. Defaults to the minimum and maximum of each column. Alternatively, these could be functions (to be applied on each column) that return a scalar. |
| <code>...</code>                  | other arguments (ignored)                                                                                                                                                                                                                                                                                                                                                       |
| <code>horizontal.axis</code>      | logical indicating whether the parallel axes should be laid out horizontally ( <code>TRUE</code> ) or vertically ( <code>FALSE</code> ).                                                                                                                                                                                                                                        |
| <code>identifier</code>           | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                             |

## Details

Produces parallel coordinate plots, which are easier to understand from an example than through a verbal description. See example for [parallel](#)

## Description

This is the default panel function for `qqmath`.

## Usage

```
panel.qqmath(x, f.value = NULL,
 distribution = qnorm,
 qtype = 7,
 groups = NULL, ...,
 tails.n = 0,
 identifier = "qqmath")
```

## Arguments

|                                    |                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>                     | vector (typically numeric, coerced if not) of data values to be used in the panel.                                                                                                                                                                                                                                                    |
| <code>f.value, distribution</code> | <code>f.value</code> defines how quantiles are calculated. See <a href="#">qqmath</a> for details.                                                                                                                                                                                                                                    |
| <code>qtype</code>                 | The type argument to be used in <a href="#">quantile</a>                                                                                                                                                                                                                                                                              |
| <code>groups</code>                | An optional grouping variable. Within each panel, one Q-Q plot is produced for every level of this grouping variable, differentiated by different graphical parameters.                                                                                                                                                               |
| <code>...</code>                   | Further arguments, often graphical parameters, eventually passed on to <a href="#">panel.xyplot</a> . Arguments <code>grid</code> and <code>abline</code> of <a href="#">panel.xyplot</a> may be particularly useful.                                                                                                                 |
| <code>tails.n</code>               | number of data points to represent exactly on each tail of the distribution. This reproduces the effect of <code>f.value = NULL</code> for the extreme data values, while approximating the remaining data. It has no effect if <code>f.value = NULL</code> . If <code>tails.n</code> is given, <code>qtype</code> is forced to be 1. |
| <code>identifier</code>            | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                   |

## Details

Creates a Q-Q plot of the data and the theoretical distribution given by `distribution`. Note that most of the arguments controlling the display can be supplied directly to the high-level `qqmath` call.

## Examples

```
set.seed(0)
xx <- rt(10000, df = 10)
qqmath(~ xx, pch = "+", distribution = qnorm,
 grid = TRUE, abline = c(0, 1),
 xlab.top = c("raw", "ppoints(100)", "tails.n = 50"),
 panel = function(..., f.value) {
 switch(panel.number(),
 panel.qqmath(..., f.value = NULL),
 panel.qqmath(..., f.value = ppoints(100)),
 panel.qqmath(..., f.value = ppoints(100), tails.n = 50))
 }, layout = c(3, 1))[c(1,1,1)]
```

**F\_1\_panel.stripplot**      *Default Panel Function for stripplot*

---

## Description

This is the default panel function for `stripplot`. Also see `panel.superpose`

## Usage

```
panel.stripplot(x, y, jitter.data = FALSE,
 factor = 0.5, amount = NULL,
 horizontal = TRUE, groups = NULL,
 ...,
 identifier = "stripplot")
```

## Arguments

|                             |                                                                                                                                                                                                                                                                                              |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x,y</code>            | coordinates of points to be plotted                                                                                                                                                                                                                                                          |
| <code>jitter.data</code>    | whether points should be jittered to avoid overplotting. The actual jittering is performed inside <code>panel.xyplot</code> , using its <code>jitter.x</code> or <code>jitter.y</code> argument (depending on the value of <code>horizontal</code> ).                                        |
| <code>factor, amount</code> | amount of jittering, see <code>jitter</code>                                                                                                                                                                                                                                                 |
| <code>horizontal</code>     | logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation. |
| <code>groups</code>         | optional grouping variable                                                                                                                                                                                                                                                                   |
| <code>...</code>            | additional arguments, passed on to <code>panel.xyplot</code>                                                                                                                                                                                                                                 |
| <code>identifier</code>     | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                          |

## Details

Creates `stripplot` (one dimensional scatterplot) of `x` for each level of `y` (or vice versa, depending on the value of `horizontal`)

|-------------------------|------------------------------------------|
| <i>F_1_panel.xyplot</i> | <i>Default Panel Function for xyplot</i> |
|-------------------------|------------------------------------------|

---

### Description

This is the default panel function for `xyplot`. Also see `panel.superpose`. The default panel functions for `splom` and `qq` are essentially the same function.

### Usage

```
panel.xyplot(x, y, type = "p",
 groups = NULL,
 pch, col, col.line, col.symbol,
 font, fontfamily, fontface,
 lty, cex, fill, lwd,
 horizontal = FALSE, ...,
 grid = FALSE, abline = NULL,
 jitter.x = FALSE, jitter.y = FALSE,
 factor = 0.5, amount = NULL,
 identifier = "xyplot")
panel.splom(..., identifier = "splom")
panel.qq(..., identifier = "qq")
```

### Arguments

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                       | variables to be plotted in the scatterplot                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>type</code>                       | character vector consisting of one or more of the following: "p", "l", "h", "b", "o", "s", "S", "r", "a", "g", "smooth", and "spline". If <code>type</code> has more than one element, an attempt is made to combine the effect of each of the components.<br><br>The behaviour if any of the first six are included in <code>type</code> is similar to the effect of <code>type</code> in <code>plot</code> ( <code>type</code> "b" is actually the same as "o"). "r" adds a linear regression line (same as <code>panel.lmline</code> , except for default graphical parameters). "smooth" adds a loess fit (same as <code>panel.loess</code> ). "spline" adds a cubic smoothing spline fit (same as <code>panel.spline</code> ). "g" adds a reference grid using <code>panel.grid</code> in the background (but using the <code>grid</code> argument is now the preferred way to do so). "a" has the effect of calling <code>panel.average</code> , which can be useful for creating interaction plots. The effect of several of these specifications depend on the value of <code>horizontal</code> .<br><br>Type "s" (and "S") sorts the values along one of the axes (depending on <code>horizontal</code> ); this is unlike the behavior in <code>plot</code> . For the latter behavior, use <code>type = "s"</code> with <code>panel = panel.points</code> .<br><br>See <code>example(xyplot)</code> and <code>demo(lattice)</code> for examples. |
| <code>groups</code>                     | an optional grouping variable. If present, <code>panel.superpose</code> will be used instead to display each subgroup                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>col, col.line, col.symbol</code>  | default colours are obtained from <code>plot.symbol</code> and <code>plot.line</code> using <code>trellis.par.get</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>font, fontface, fontfamily</code> | font used when <code>pch</code> is a character                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pch, lty, cex, lwd, fill</code> | other graphical parameters. <code>fill</code> serves the purpose of <code>bg</code> in <a href="#">points</a> for certain values of <code>pch</code>                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>horizontal</code>               | A logical flag controlling the orientation for certain type's, e.g., "h", "s", ans "S".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>...</code>                      | Extra arguments, if any, for <code>panel.xyplot</code> . In most cases <code>panel.xyplot</code> ignores these. For types "r" and "smooth", these are passed on to <code>panel.lmline</code> and <code>panel.loess</code> respectively.                                                                                                                                                                                                                                                                                                                                                          |
| <code>grid</code>                     | A logical flag, character string, or list specifying whether and how a background grid should be drawn. This provides the same functionality as <code>type="g"</code> , but is the preferred alternative as the effect <code>type="g"</code> is conceptually different from that of other type values (which are all data-dependent). Using the <code>grid</code> argument also allows more flexibility.<br><br>Most generally, <code>grid</code> can be a list of arguments to be supplied to <a href="#">panel.grid</a> , which is called with those arguments. Three shortcuts are available: |
|                                       | <code>TRUE</code> : roughly equivalent to <code>list(h = -1, v = -1)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                       | <code>"h"</code> : roughly equivalent to <code>list(h = -1, v = 0)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                                       | <code>"v"</code> : roughly equivalent to <code>list(h = 0, v = -1)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|                                       | No grid is drawn if <code>grid = FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>abline</code>                   | A numeric vector or list, specifying arguments arguments for <a href="#">panel.abline</a> , which is called with those arguments. If specified as a (possibly named) numeric vector, <code>abline</code> is coerced to a list. This allows arguments of the form <code>abline = c(0, 1)</code> , which adds the diagonal line, or <code>abline = c(h = 0, v = 0)</code> , which adds the x- and y-axes to the plot. Use the list form for finer control; e.g., <code>abline = list(h = 0, v = 0, col = "grey")</code> .<br><br>For more flexibility, use <a href="#">panel.abline</a> directly.  |
| <code>jitter.x, jitter.y</code>       | logical, whether the data should be jittered before being plotted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>factor, amount</code>           | controls amount of jittering.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>identifier</code>               | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Details

Creates scatterplot of `x` and `y`, with various modifications possible via the `type` argument. `panel.qq` draws a 45 degree line before calling `panel.xyplot`.

Note that most of the arguments controlling the display can be supplied directly to the high-level (e.g. [xyplot](#)) call.

## Examples

```

types.plain <- c("p", "l", "o", "r", "g", "s", "S", "h", "a", "smooth")
types.horiz <- c("s", "S", "h", "a", "smooth")
horiz <- rep(c(FALSE, TRUE), c(length(types.plain), length(types.horiz)))

types <- c(types.plain, types.horiz)

x <- sample(seq(-10, 10, length.out = 15), 30, TRUE)
y <- x + 0.25 * (x + 1)^2 + rnorm(length(x), sd = 5)

xyplot(y ~ x | gl(1, length(types)),
 xlab = "type",
 ylab = list(c("horizontal=TRUE", "horizontal=FALSE"), y = c(1/6, 4/6)),
 as.table = TRUE, layout = c(5, 3),
 between = list(y = c(0, 1)),
 strip = function(...) {
 panel.fill(trellis.par.get("strip.background")$col[1])
 type <- types[panel.number()]
 grid::grid.text(label = sprintf('%s', type),
 x = 0.5, y = 0.5)
 grid::grid.rect()
 },
 scales = list(alternating = c(0, 2), tck = c(0, 0.7), draw = FALSE),
 par.settings =
 list(layout.widths = list(strip.left = c(1, 0, 0, 0, 0))),
 panel = function(...) {
 type <- types[panel.number()]
 horizontal <- horiz[panel.number()]
 panel.xyplot(...,
 type = type,
 horizontal = horizontal)
 })[rep(1, length(types))]

```

## Description

These functions are intended to replace common low level traditional graphics functions, primarily for use in panel functions. The originals can not be used (at least not easily) because lattice panel functions need to use grid graphics. Low level drawing functions in grid can be used directly as well, and is often more flexible. These functions are provided for convenience and portability.

## Usage

```

lplot.xy(xy, type, pch, lty, col, cex, lwd,
 font, fontfamily, fontface,
 col.line, col.symbol, alpha, fill,
 origin = 0, ..., identifier, name.type)

llines(x, ...)
lpoints(x, ...)

```

```

ltext(x, ...)

Default S3 method:
llines(x, y = NULL, type = "l",
 col, alpha, lty, lwd, ..., identifier, name.type)
Default S3 method:
lpoints(x, y = NULL, type = "p", col, pch, alpha, fill,
 font, fontfamily, fontface, cex, ..., identifier, name.type)
Default S3 method:
ltext(x, y = NULL, labels = seq_along(x),
 col, alpha, cex, srt = 0,
 lineheight, font, fontfamily, fontface,
 adj = c(0.5, 0.5), pos = NULL, offset = 0.5, ..., identifier, name.type)

lsegments(x0, y0, x1, y1, x2, y2,
 col, alpha, lty, lwd,
 font, fontface, ..., identifier, name.type)
lrect(xleft, ybottom, xright, ytop,
 x = (xleft + xright) / 2,
 y = (ybottom + ytop) / 2,
 width = xright - xleft,
 height = ytop - ybottom,
 col = "transparent",
 border = "black",
 lty = 1, lwd = 1, alpha = 1,
 just = "center",
 hjust = NULL, vjust = NULL,
 ..., identifier, name.type)
larrows(x0 = NULL, y0 = NULL, x1, y1, x2 = NULL, y2 = NULL,
 angle = 30, code = 2, length = 0.25, unit = "inches",
 ends = switch(code, "first", "last", "both"),
 type = "open",
 col = add.line$col,
 alpha = add.line$alpha,
 lty = add.line$lty,
 lwd = add.line$lwd,
 fill = NULL, ..., identifier, name.type)
lpolygon(x, y = NULL,
 border = "black", col = "transparent", fill = NULL,
 font, fontface, ..., identifier, name.type)

panel.lines(...)
panel.points(...)
panel.segments(...)
panel.text(...)
panel.rect(...)
panel.arrows(...)
panel.polygon(...)

```

### Arguments

`x, y, x0, y0, x1, y1, x2, y2, xy`  
 locations. `x2` and `y2` are available for for S compatibility.

|                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| length, unit                                                                                       | determines extent of arrow head. length specifies the length in terms of unit, which can be any valid grid unit as long as it doesn't need a data argument. unit defaults to inches, which is the only option in the base version of the function, <a href="#">arrows</a> .                                                                                                                                                                                                                                                                                                                                                                           |
| angle, code, type, labels, srt, adj, pos, offset                                                   | arguments controlling behaviour. See respective base functions for details. For <a href="#">larrow</a> s and <a href="#">panel.larrow</a> s, type is either "open" or "closed", indicating the type of arrowhead.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ends                                                                                               | serves the same function as code, using descriptive names rather than integer codes. If specified, this overrides code                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| col, alpha, lty, lwd, fill, pch, cex, lineheight, font, fontfamily, fontface, col.line, col.symbol | graphical parameters. fill applies to points when pch is in 21:25 and specifies the fill color, similar to the bg argument in the base graphics function <a href="#">points</a> . For devices that support alpha-transparency, a numeric argument alpha between 0 and 1 can controls transparency. Be careful with this, since for devices that do not support alpha-transparency, nothing will be drawn at all if this is set to anything other than 0.<br>fill, font and fontface are included in <a href="#">lpolygon</a> and <a href="#">lsegments</a> only to ensure that they are not passed down (as <a href="#">gpar</a> does not like them). |
| origin                                                                                             | for type="h" or type="H", the value to which lines drop down.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Details

These functions are meant to be grid replacements of the corresponding base R graphics functions, to allow existing Trellis code to be used with minimal modification. The functions [panel.\\*](#) are essentially identical to the [l\\*](#) versions, are recommended for use in new code (as opposed to ported code) as they have more readable names.

See the documentation of the base functions for usage. Not all arguments are always supported. All these correspond to the default methods only.

## Note

There is a new type="H" option wherever appropriate, which is similar to type="h", but with horizontal lines.

### Description

These are predefined panel functions available in lattice for use in constructing new panel functions (often on-the-fly).

### Usage

```

panel.abline(a = NULL, b = 0,
 h = NULL, v = NULL,
 reg = NULL, coef = NULL,
 col, col.line, lty, lwd, alpha, type,
 ...,
 reference = FALSE,
 identifier = "abline")
panel.refline(...)

panel.curve(expr, from, to, n = 101,
 curve.type = "l",
 col, lty, lwd, type,
 ...,
 identifier = "curve")
panel.rug(x = NULL, y = NULL,
 regular = TRUE,
 start = if (regular) 0 else 0.97,
 end = if (regular) 0.03 else 1,
 x.units = rep("npc", 2),
 y.units = rep("npc", 2),
 col, col.line, lty, lwd, alpha,
 ...,
 identifier = "rug")
panel.average(x, y, fun = mean, horizontal = TRUE,
 lwd, lty, col, col.line, type,
 ...,
 identifier = "linejoin")
panel.linejoin(x, y, fun = mean, horizontal = TRUE,
 lwd, lty, col, col.line, type,
 ...,
 identifier = "linejoin")

panel.fill(col, border, ..., identifier = "fill")
panel.grid(h=3, v=3, col, col.line, lty, lwd, x, y, ..., identifier = "grid")
panel.lmline(x, y, ..., identifier = "lmline")
panel.mathdensity(dmath = dnorm, args = list(mean=0, sd=1),
 n = 50, col, col.line, lwd, lty, type,
```

```
..., identifier = "mathdensity")
```

### Arguments

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, y             | Variables defining the contents of the panel. In <code>panel.grid</code> these are optional and are used only to choose an appropriate method of <code>pretty</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| a, b             | Coefficients of the line to be added by <code>panel.abline</code> . <code>a</code> can be a vector of length 2, representing the coefficients of the line to be added, in which case <code>b</code> should be missing. <code>a</code> can also be an appropriate ‘regression’ object, i.e., an object which has a <code>coef</code> method that returns a length 2 numeric vector. The corresponding line will be plotted. The <code>reg</code> argument overrides <code>a</code> if specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| coef             | Coefficients of the line to be added as a vector of length 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| reg              | A (linear) regression object, with a <code>coef</code> method that gives the coefficients of the corresponding regression line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| h, v             | For <code>panel.abline</code> , these are numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates.<br>For <code>panel.grid</code> , these usually specify the number of horizontal and vertical reference lines to be added to the plot. Alternatively, they can be negative numbers. <code>h=-1</code> and <code>v=-1</code> are intended to make the grids aligned with the axis labels. This doesn’t always work; all that actually happens is that the locations are chosen using <code>pretty</code> , which is also how the label positions are chosen in the most common cases (but not for factor variables, for instance). <code>h</code> and <code>v</code> can be negative numbers other than -1, in which case <code>-h</code> and <code>-v</code> (as appropriate) is supplied as the <code>n</code> argument to <code>pretty</code> .<br>If <code>x</code> and/or <code>y</code> are specified in <code>panel.grid</code> , they will be used to select an appropriate method for <code>pretty</code> . This is particularly useful while plotting date-time objects. |
| reference        | A logical flag determining whether the default graphical parameters for <code>panel.abline</code> should be taken from the “reference.line” parameter settings. The default is to take them from the “add.line” settings. The <code>panel.refline</code> function is a wrapper around <code>panel.abline</code> that calls it with <code>reference = TRUE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| expr             | An expression considered as a function of <code>x</code> , or a function, to be plotted as a curve.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| n                | The number of points to use for drawing the curve.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| from, to         | optional lower and upper x-limits of curve. If missing, limits of current panel are used                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| curve.type       | Type of curve (“p” for points, etc), passed to <code>llines</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| regular          | A logical flag indicating whether the ‘rug’ is to be drawn on the ‘regular’ side (left / bottom) or not (right / top).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| start, end       | endpoints of rug segments, in normalized parent coordinates (between 0 and 1). Defaults depend on value of <code>regular</code> , and cover 3% of the panel width and height.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| x.units, y.units | Character vectors, replicated to be of length two. Specifies the (grid) units associated with <code>start</code> and <code>end</code> above. <code>x.units</code> and <code>y.units</code> are for the rug on the x-axis and y-axis respectively (and thus are associated with <code>start</code> and <code>end</code> values on the y and x scales respectively).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|            |                                                                                                                                                                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | col, col.line, lty, lwd, alpha, border<br>Graphical parameters.                                                                                                                                                                                            |
| type       | Usually ignored by the panel functions documented here; the argument is present only to make sure an explicitly specified type argument (perhaps meant for another function) does not affect the display.                                                  |
| fun        | The function that will be applied to the subset of x values (or y if horizontal is FALSE) determined by the unique values of y (x).                                                                                                                        |
| horizontal | A logical flag. If FALSE, the plot is ‘transposed’ in the sense that the roles of x and y are switched; x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation. |
| dmath      | A vectorized function that produces density values given a numeric vector named x, e.g., <a href="#">dnorm</a> .                                                                                                                                           |
| args       | A list giving additional arguments to be passed to dmath.                                                                                                                                                                                                  |
| ...        | Further arguments, typically graphical parameters, passed on to other low-level functions as appropriate. Color can usually be specified by col, col.line, and col.symbol, the last two overriding the first for lines and points respectively.            |
| identifier | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                        |

## Details

`panel.abline` adds a line of the form  $y = a + b * x$ , or vertical and/or horizontal lines. Graphical parameters are obtained from the “add.line” settings by default. `panel.refline` is similar, but uses the “reference.line” settings for the defaults.

`panel.grid` draws a reference grid.

`panel.curve` adds a curve, similar to what `curve` does with `add = TRUE`. Graphical parameters for the curve are obtained from the “add.line” setting.

`panel.average` treats one of x and y as a factor (according to the value of `horizontal`), calculates fun applied to the subsets of the other variable determined by each unique value of the factor, and joins them by a line. Can be used in conjunction with `panel.xyplot`, and more commonly with `panel.superpose` to produce interaction plots.

`panel.linejoin` is an alias for `panel.average`. It is retained for back-compatibility, and may go away in future.

`panel.mathdensity` plots a (usually theoretical) probability density function. This can be useful in conjunction with `histogram` and `densityplot` to visually assess goodness of fit (note, however, that `qqmath` is more suitable for this).

`panel.rug` adds a *rug* representation of the (marginal) data to the panel, much like `rug`.

`panel.lmline(x, y)` is equivalent to `panel.abline(lm(y ~ x))`.

## Examples

```

Interaction Plot

bwplot(yield ~ site, barley, groups = year,
 panel = function(x, y, groups, subscripts, ...) {
 panel.grid(h = -1, v = 0)
 panel.stripplot(x, y, ..., jitter.data = TRUE,
 groups = groups, subscripts = subscripts)
 panel.superpose(x, y, ..., panel.groups = panel.average,
 groups = groups, subscripts = subscripts)
 },
 auto.key =
 list(points = FALSE, lines = TRUE, columns = 2))

Superposing a fitted normal density on a Histogram

histogram(~ height | voice.part, data = singer, layout = c(2, 4),
 type = "density", border = "transparent", col.line = "grey60",
 xlab = "Height (inches)",
 ylab = "Density Histogram\n with Normal Fit",
 panel = function(x, ...) {
 panel.histogram(x, ...)
 panel.mathdensity(dmath = dnorm,
 args = list(mean=mean(x),sd=sd(x)), ...)
 })

```

## F\_2\_panel.loess

*Panel Function to Add a LOESS Smooth*

## Description

A predefined panel function that can be used to add a LOESS smooth based on the provided data.

## Usage

```
panel.loess(x, y, span = 2/3, degree = 1,
 family = c("symmetric", "gaussian"),
 evaluation = 50,
 lwd, lty, col, col.line, type,
 horizontal = FALSE,
 ..., identifier = "loess")
```

## Arguments

|                         |                                                                                                                                                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, y                    | Variables defining the data to be used.                                                                                                                         |
| lwd, lty, col, col.line | Graphical parameters for the added line. col.line overrides col.                                                                                                |
| type                    | Ignored. The argument is present only to make sure that an explicitly specified type argument (perhaps meant for another function) does not affect the display. |

|                                  |                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| span, degree, family, evaluation | Arguments to <a href="#">loess.smooth</a> , for which panel.loess is essentially a wrapper.                                                                                                                                                                                                                                                                          |
| horizontal                       | A logical flag controlling which variable is to be treated as the predictor (by default x) and which as the response (by default y). If TRUE, the plot is ‘transposed’ in the sense that y becomes the predictor and x the response. (The name ‘horizontal’ may seem an odd choice for this argument, and originates from similar usage in <a href="#">bwplot</a> ). |
| ...                              | Extra arguments, passed on to <a href="#">panel.lines</a> .                                                                                                                                                                                                                                                                                                          |
| identifier                       | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                  |

**Value**

The object returned by [loess.smooth](#).

F\_2\_panel.qqmathline    *Useful panel function with qqmath*

**Description**

Useful panel function with qqmath. Draws a line passing through the points (usually) determined by the .25 and .75 quantiles of the sample and the theoretical distribution.

**Usage**

```
panel.qqmathline(x, y = x,
 distribution = qnorm,
 probs = c(0.25, 0.75),
 qtype = 7,
 groups = NULL,
 ...,
 identifier = "qqmathline")
```

**Arguments**

|              |                                                                                                                       |
|--------------|-----------------------------------------------------------------------------------------------------------------------|
| x            | The original sample, possibly reduced to a fewer number of quantiles, as determined by the f.value argument to qqmath |
| y            | an alias for x for backwards compatibility                                                                            |
| distribution | quantile function for reference theoretical distribution.                                                             |
| probs        | numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.         |
| qtype        | the type of quantile computation used in <a href="#">quantile</a>                                                     |

|            |                                                                                                     |
|------------|-----------------------------------------------------------------------------------------------------|
| groups     | optional grouping variable. If non-null, a line will be drawn for each group.                       |
| ...        | other arguments.                                                                                    |
| identifier | A character string that is prepended to the names of grobs that are created by this panel function. |

**F\_2\_panel.smoothScatter**

*Lattice panel function analogous to smoothScatter*

**Description**

This function allows the user to place `smoothScatter` plots in lattice graphics.

**Usage**

```
panel.smoothScatter(x, y = NULL,
 nbin = 64, cuts = 255,
 bandwidth,
 colramp,
 nrpoints = 100,
 transformation = function(x) x^0.25,
 pch = ".",
 cex = 1, col="black",
 range.x,
 ...,
 raster = FALSE,
 subscripts,
 identifier = "smoothScatter")
```

**Arguments**

|           |                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | Numeric vector containing x-values or n by 2 matrix containing x and y values.                                                                                                          |
| y         | Numeric vector containing y-values (optional). The length of x must be the same as that of y.                                                                                           |
| nbin      | Numeric vector of length 1 (for both directions) or 2 (for x and y separately) containing the number of equally spaced grid points for the density estimation.                          |
| cuts      | number of cuts defining the color gradient                                                                                                                                              |
| bandwidth | Numeric vector: the smoothing bandwidth. If missing, these functions come up with a more or less useful guess. This parameter then gets passed on to the function <code>bkde2D</code> . |
| colramp   | Function accepting an integer n as an argument and returning n colors.                                                                                                                  |

|                       |                                                                                                                                                                                                                                                                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nrpoints</b>       | Numeric vector of length 1 giving number of points to be superimposed on the density image. The first <b>nrpoints</b> points from those areas of lowest regional densities will be plotted. Adding points to the plot allows for the identification of outliers. If all points are to be plotted, choose <b>nrpoints</b> = Inf. |
| <b>transformation</b> | Function that maps the density scale to the color scale.                                                                                                                                                                                                                                                                        |
| <b>pch, cex</b>       | graphical parameters for the <b>nrpoints</b> “outlying” points shown in the display                                                                                                                                                                                                                                             |
| <b>range.x</b>        | see <b>bkde2D</b> for details.                                                                                                                                                                                                                                                                                                  |
| <b>col</b>            | <b>points</b> color parameter                                                                                                                                                                                                                                                                                                   |
| <b>...</b>            | Further arguments that are passed on to <b>panel.levelplot</b> .                                                                                                                                                                                                                                                                |
| <b>raster</b>         | logical; if TRUE, <b>panel.levelplot.raster</b> is used, making potentially smaller output files.                                                                                                                                                                                                                               |
| <b>subscripts</b>     | ignored, but necessary for handling of ...in certain situations. Likely to be removed in future.                                                                                                                                                                                                                                |
| <b>identifier</b>     | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                             |

## Details

This replicates the display part of the **smoothScatter** function by replacing standard graphics calls by grid-compatible ones.

## Value

The function is called for its side effects, namely the production of the appropriate plots on a graphics device.

## Author(s)

Deepayan Sarkar <[deepayan.sarkar@r-project.org](mailto:deepayan.sarkar@r-project.org)>

## Examples

```
ddf <- as.data.frame(matrix(rnorm(40000), ncol = 4) + 3 * rnorm(10000))
ddf[, c(2,4)] <- (-ddf[, c(2,4)])
xyplot(V1 ~ V2 + V3, ddf, outer = TRUE,
 panel = panel.smoothScatter, aspect = "iso")
splom(ddf, panel = panel.smoothScatter, nbin = 64, raster = TRUE)
```

## Description

A predefined panel function that can be used to add a spline smooth based on the provided data.

**Usage**

```
panel.spline(x, y, npoints = 101,
 lwd = plot.line$lwd,
 lty = plot.line$lty,
 col, col.line = plot.line$col,
 type,
 horizontal = FALSE, ...,
 keep.data = FALSE,
 identifier = "spline")
```

**Arguments**

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                    | Variables defining the data to be used.                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>npoints</code>                 | The number of equally spaced points within the range of the predictor at which the fitted model is evaluated for plotting.                                                                                                                                                                                                                                                                                              |
| <code>lwd, lty, col, col.line</code> | Graphical parameters for the added line. <code>col.line</code> overrides <code>col</code> .                                                                                                                                                                                                                                                                                                                             |
| <code>type</code>                    | Ignored. The argument is present only to make sure that an explicitly specified <code>type</code> argument (perhaps meant for another function) does not affect the display.                                                                                                                                                                                                                                            |
| <code>horizontal</code>              | A logical flag controlling which variable is to be treated as the predictor (by default <code>x</code> ) and which as the response (by default <code>y</code> ). If TRUE, the plot is ‘transposed’ in the sense that <code>y</code> becomes the predictor and <code>x</code> the response. (The name ‘horizontal’ may seem an odd choice for this argument, and originates from similar usage in <code>bwplot</code> ). |
| <code>keep.data</code>               | Passed on to <code>smooth.spline</code> . The default here (FALSE) is different, and results in the original data not being retained in the fitted spline model. It may be useful to set this to TRUE if the return value of <code>panel.spline</code> , which is the fitted model as returned by <code>smooth.spline</code> , is to be used for subsequent computations.                                               |
| <code>...</code>                     | Extra arguments, passed on to <code>smooth.spline</code> and <code>panel.lines</code> as appropriate.                                                                                                                                                                                                                                                                                                                   |
| <code>identifier</code>              | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                                                                                                                                                     |

**Value**

The fitted model as returned by `smooth.spline`.

**F\_2\_panel.superpose**      *Panel Function for Display Marked by groups*

---

## Description

These are panel functions for Trellis displays useful when a grouping variable is specified for use within panels. The x (and y where appropriate) variables are plotted with different graphical parameters for each distinct value of the grouping variable.

## Usage

```
panel.superpose(x, y = NULL, subscripts, groups,
 panel.groups = "panel.xyplot",
 ...,
 col, col.line, col.symbol,
 pch, cex, fill, font,
 fontface, fontfamily,
 lty, lwd, alpha,
 type = "p", grid = FALSE,
 distribute.type = FALSE)
panel.superpose.2(..., distribute.type = TRUE)

panel.superpose.plain(...,
 col, col.line, col.symbol,
 pch, cex, fill, font,
 fontface, fontfamily,
 lty, lwd, alpha)
```

## Arguments

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x,y</code>          | Coordinates of the points to be displayed. Usually numeric.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>panel.groups</code> | The panel function to be used for each subgroup of points. Defaults to <code>panel.xyplot</code> .<br>To be able to distinguish between different levels of the originating group inside <code>panel.groups</code> , it will be supplied two special arguments called <code>group.number</code> and <code>group.value</code> which will hold the numeric code and factor level corresponding to the current level of groups. No special care needs to be taken when writing a <code>panel.groups</code> function if this feature is not used. |
| <code>subscripts</code>   | An integer vector of subscripts giving indices of the x and y values in the original data source. See the corresponding entry in <code>xyplot</code> for details.                                                                                                                                                                                                                                                                                                                                                                             |
| <code>groups</code>       | A grouping variable. Different graphical parameters will be used to plot the subsets of observations given by each distinct value of <code>groups</code> . The default graphical parameters are obtained from the " <code>superpose.symbol</code> " and " <code>superpose.line</code> " settings using <code>trellis.par.get</code> wherever appropriate.                                                                                                                                                                                     |
| <code>type</code>         | Usually a character vector specifying how each group should be drawn. Formally, it is passed on to the <code>panel.groups</code> function, which must know what to do with it. By default, <code>panel.groups</code> is <code>panel.xyplot</code> , whose help page describes the admissible values.                                                                                                                                                                                                                                          |

The functions `panel.superpose` and `panel.superpose.2` differ only in the default value of `distribute.type`, which controls the way the `type` argument is interpreted. If `distribute.type = FALSE`, then the interpretation is the same as for `panel.xyplot` for each of the unique groups. In other words, if `type` is a vector, all the individual components are honoured concurrently. If `distribute.type = TRUE`, `type` is replicated to be as long as the number of unique values in `groups`, and one component used for the points corresponding to the each different group. Even in this case, it is possible to request multiple types per group, specifying `type` as a list, each component being the desired type vector for the corresponding group.

If `distribute.type = FALSE`, any occurrence of "g" in `type` causes a grid to be drawn, and all such occurrences are removed before `type` is passed on to `panel.groups`.

|                                         |                                                                                                                                                                         |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>grid</code>                       | Logical flag specifying whether a background reference grid should be drawn. See <a href="#">panel.xyplot</a> for details.                                              |
| <code>col</code>                        | A vector color specification. See Details.                                                                                                                              |
| <code>col.line</code>                   | A vector color specification. See Details.                                                                                                                              |
| <code>col.symbol</code>                 | A vector color specification. See Details.                                                                                                                              |
| <code>pch</code>                        | A vector plotting character specification. See Details.                                                                                                                 |
| <code>cex</code>                        | A vector size factor specification. See Details.                                                                                                                        |
| <code>fill</code>                       | A vector fill color specification. See Details.                                                                                                                         |
| <code>font, fontface, fontfamily</code> | A vector color specification. See Details.                                                                                                                              |
| <code>lty</code>                        | A vector color specification. See Details.                                                                                                                              |
| <code>lwd</code>                        | A vector color specification. See Details.                                                                                                                              |
| <code>alpha</code>                      | A vector alpha-transparency specification. See Details.                                                                                                                 |
| <code>...</code>                        | Extra arguments. Passed down to <code>panel.superpose</code> from <code>panel.superpose.2</code> , and to <code>panel.groups</code> from <code>panel.superpose</code> . |
| <code>distribute.type</code>            | logical controlling interpretation of the <code>type</code> argument.                                                                                                   |

## Details

`panel.superpose` divides up the `x` (and optionally `y`) variable(s) by the unique values of `groups[subscripts]`, and plots each subset with different graphical parameters. The graphical parameters (`col.symbol`, `pch`, etc.) are usually supplied as suitable atomic vectors, but can also be lists. When `panel.groups` is called for the `i`-th level of `groups`, the corresponding element of each graphical parameter is passed to it. In the list form, the individual components can themselves be vectors.

The actual plot for each subgroup is created by the `panel.groups` function. With the default `panel.groups`, the `col` argument is overridden by `col.line` and `col.symbol` for lines and points respectively, which default to the "superpose.line" and "superpose.symbol" settings. However, `col` will still be supplied as an argument to `panel.groups` functions that make use of it, with a default of "black". The defaults of other graphical parameters are also taken from the "superpose.line" and "superpose.symbol" settings as appropriate. The `alpha` parameter takes it default from the "superpose.line" setting.

`panel.superpose` and `panel.superpose.2` differ essentially in how `type` is interpreted by default. The default behaviour in `panel.superpose` is the opposite of that in S, which is the same as that of `panel.superpose.2`.

`panel.superpose.plain` is the same as `panel.superpose`, except that the default settings for the style arguments are the same for all groups and are taken from the default plot style. It is used in [xyplot.ts](#).

Different functions when used as `panel.groups` gives different types of plots, for example [panel.xyplot](#), [panel.dotplot](#) and [panel.average](#) (This can be used to produce interaction plots).

See [Lattice](#) for an overview of the package, and [xyplot](#) for common arguments (in particular, the discussion of the extended formula interface and the `groups` argument).

`F_2_panel.violin`

*Panel Function to create Violin Plots*

### Description

This is a panel function that can create a violin plot. It is typically used in a high-level call to `bwplot`.

### Usage

```
panel.violin(x, y, box.ratio = 1, box.width,
 horizontal = TRUE,
 alpha, border, lty, lwd, col,
 varwidth = FALSE,
 bw, adjust, kernel, window,
 width, n = 50, from, to, cut,
 na.rm, ...,
 identifier = "violin")
```

### Arguments

|                                           |                                                                                                                                                                                                                                                         |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x, y</code>                         | numeric vector or factor. Violin plots are drawn for each unique value of <code>y</code> ( <code>x</code> ) if <code>horizontal</code> is <code>TRUE</code> ( <code>FALSE</code> )                                                                      |
| <code>box.ratio</code>                    | ratio of the thickness of each violin and inter violin space                                                                                                                                                                                            |
| <code>box.width</code>                    | thickness of the violins in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.         |
| <code>horizontal</code>                   | logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. See documentation of <a href="#">bwplot</a> for a fuller explanation. |
| <code>alpha, border, lty, lwd, col</code> | graphical parameters controlling the violin. Defaults are taken from the “ <code>plot.polygon</code> ” settings.                                                                                                                                        |

|                                                                         |                                                                                                                                                                                                                                                                                    |
|-------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>varwidth</code>                                                   | logical. If FALSE, the densities are scaled separately for each group, so that the maximum value of the density reaches the limit of the allocated space for each violin (as determined by <code>box.ratio</code> ). If TRUE, densities across violins will have comparable scale. |
| <code>bw, adjust, kernel, window, width, n, from, to, cut, na.rm</code> | arguments to <code>density</code> , passed on as appropriate                                                                                                                                                                                                                       |
| <code>...</code>                                                        | arguments passed on to <code>density</code> .                                                                                                                                                                                                                                      |
| <code>identifier</code>                                                 | A character string that is prepended to the names of grobs that are created by this panel function.                                                                                                                                                                                |

## Details

Creates Violin plot of x for every level of y. Note that most arguments controlling the display can be supplied to the high-level (typically `bwplot`) call directly.

## Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

#### **See Also**

## bwplot, density

## Examples

```

bwplot(voice.part ~ height, singer,
 panel = function(..., box.ratio) {
 panel.violin(..., col = "transparent",
 varwidth = FALSE, box.ratio = box.ratio)
 panel.bwplot(..., fill = NULL, box.ratio = .1)
 })

```

### F\_3\_prepelan.default    *Default Prepanel Functions*

## Description

These prepanel functions are used as fallback defaults in various high level plot functions in Lattice. These are rarely useful to normal users but may be helpful in developing new displays.

## Usage

```

..., zoom = 0.8)
prepanel.default.levelplot(x, y, subscripts, ...)
prepanel.default.qqmath(x, f.value, distribution, qtype,
 groups, subscripts, ..., tails.n = 0)
prepanel.default.densityplot(x, darg, groups, weights, subscripts, ...)
prepanel.default.parallel(x, y, z, ..., horizontal.axis)
prepanel.default.splom(z, ...)

```

## Arguments

**x, y** x and y values, numeric or factor  
**horizontal** logical, applicable when one of the variables is to be treated as categorical (factor or shingle).  
**horizontal.axis** logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).  
**nlevels** number of levels of such a categorical variable.  
**origin, stack** for barcharts or the type="h" plot type  
**breaks, equal.widths, type, nint** details of histogram calculations. type has a different meaning in prepanel.default.xyplot (see [panel.xyplot](#))  
**groups, subscripts** See [xyplot](#). Whenever appropriate, calculations are done separately for each group and then combined.  
**weights** numeric vector of weights for the density calculations. If this is specified, it is subsetted by subscripts to match it to x.  
**perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, panel.aspect, zoom** see [panel.cloud](#)  
**f.value, distribution, tails.n** see [panel.qqmath](#)  
**darg** list of arguments passed to [density](#)  
**z** see [panel.parallel](#) and [panel.pairs](#)  
**qtype** type of [quantile](#)  
**...** other arguments, usually ignored

## Value

A list with components `xlim`, `ylim`, `dx` and `dy`, and possibly `xat` and `yat`, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described in the help page for [xyplot](#).

## Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

## See Also

[xyplot](#), [banking](#), [Lattice](#). See documentation of corresponding panel functions for more details about the arguments.

---

F\_3\_prepelan.functions*Useful Prepanel Function for Lattice*

---

**Description**

These are predefined prepanel functions available in Lattice.

**Usage**

```
prepanel.lmline(x, y, ...)
prepanel.qqmathline(x, y = x, distribution = qnorm,
 probs = c(0.25, 0.75), qtype = 7,
 groups, subscripts,
 ...)
prepanel.loess(x, y, span, degree, family, evaluation,
 horizontal = FALSE, ...)
prepanel.spline(x, y, npoints = 101,
 horizontal = FALSE, ...,
 keep.data = FALSE)
```

**Arguments**

|                                  |                                                                                                                                                                                                                           |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x, y                             | x and y values, numeric or factor                                                                                                                                                                                         |
| distribution                     | quantile function for theoretical distribution. This is automatically passed in when this is used as a prepanel function in qqmath.                                                                                       |
| qtype                            | type of <a href="#">quantile</a>                                                                                                                                                                                          |
| probs                            | numeric vector of length two, representing probabilities. If used with aspect="xy", the aspect ratio will be chosen to make the line passing through the corresponding quantile pairs as close to 45 degrees as possible. |
| span, degree, family, evaluation | Arguments controlling the underlying <a href="#">loess</a> smooth.                                                                                                                                                        |
| horizontal, npoints              | See documentation for corresponding panel function.                                                                                                                                                                       |
| keep.data                        | Ignored. Present to capture argument of the same name in <a href="#">smooth.spline</a> .                                                                                                                                  |
| groups, subscripts               | See <a href="#">xyplot</a> . Whenever appropriate, calculations are done separately for each group and then combined.                                                                                                     |
| ...                              | Other arguments. These are passed on to other functions if appropriate (in particular, <a href="#">smooth.spline</a> ), and ignored otherwise.                                                                            |

**Details**

All these prepanel functions compute the limits to be large enough to contain all points as well as the relevant smooth.

In addition, prepanel.lmline computes the dx and dy such that it reflects the slope of the linear regression line; for prepanel.qqmathline, this is the slope of the line passing through the quantile pairs specified by probs. For prepanel.loess and prepanel.spline, dx and dy reflect the piecewise slopes of the nonlinear smooth.

**Value**

usually a list with components `xlim`, `ylim`, `dx` and `dy`, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described under [xyplot](#). There are also several prepanel functions that serve as the default for high level functions, see [prepanel.default.xyplot](#)

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

`G_axis.default`

*Default axis annotation utilities*

**Description**

Lattice funtions provide control over how the plot axes are annotated through a common interface. There are two levels of control. The `xscale.components` and `yscale.components` arguments can be functions that determine tick mark locations and labels given a packet. For more direct control, the `axis` argument can be a function that actually draws the axes. The functions documented here are the defaults for these arguments. They can additonally be used as components of user written replacements.

**Usage**

```
xscale.components.default(lim,
 packet.number = 0,
 packet.list = NULL,
 top = TRUE,
 ...)
yscale.components.default(lim,
 packet.number = 0,
 packet.list = NULL,
 right = TRUE,
 ...)
axis.default(side = c("top", "bottom", "left", "right"),
 scales, components, as.table,
 labels = c("default", "yes", "no"),
 ticks = c("default", "yes", "no"),
 ..., prefix)
```

**Arguments**

- |                  |                                                                                                                                                                                                                                                                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>lim</code> | the range of the data in that packet (data subset corresponding to a combination of levels of the conditioning variable). The range is not necessarily numeric; e.g. for factors, they could be character vectors representing levels, and for the various date-time representations, they could be vectors of length 2 with the corresponding class. |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|               |                                                                                                                                                                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| packet.number | which packet (counted according to the packet order, described in <a href="#">print.trellis</a> ) is being processed. In cases where all panels have the same limits, this function is called only once (rather than once for each packet), in which case this argument will have the value 0. |
| packet.list   | list, as long as the number of packets, giving all the actual packets. Specifically, each component is the list of arguments given to the panel function when and if that packet is drawn in a panel. (This has not yet been implemented.)                                                     |
| top, right    | the value of the top and right components of the result, as appropriate. See below for interpretation.                                                                                                                                                                                         |
| side          | on which side the axis is to be drawn. The usual partial matching rules apply.                                                                                                                                                                                                                 |
| scales        | the appropriate component of the scales argument supplied to the high level function, suitably standardized.                                                                                                                                                                                   |
| components    | list, similar to those produced by <code>xscale.components.default</code> and <code>yscale.components.default</code> .                                                                                                                                                                         |
| as.table      | the <code>as.table</code> argument in the high level function.                                                                                                                                                                                                                                 |
| labels        | whether labels are to be drawn. By default, the rules determined by scales are used.                                                                                                                                                                                                           |
| ticks         | whether labels are to be drawn. By default, the rules determined by scales are used.                                                                                                                                                                                                           |
| ...           | many other arguments may be supplied, and are passed on to other internal functions.                                                                                                                                                                                                           |
| prefix        | A character string identifying the plot being drawn (see <a href="#">print.trellis</a> ). Used to retrieve location of current panel in the overall layout, so that axes can be drawn appropriately.                                                                                           |

## Details

These functions are part of a new API introduced in lattice 0.14 to provide the user more control over how axis annotation is done. While the API has been designed in anticipation of use that was previously unsupported, the implementation has initially focused on reproducing existing capabilities, rather than test new features. At the time of writing, several features are unimplemented. If you require them, please contact the maintainer.

## Value

`xscale.components.default` and `yscale.components.default` return a list of the form suitable as the `components` argument of `axis.default`. Valid components in the return value of `xscale.components.default` are:

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| num.limit | A numeric limit for the box.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| bottom    | A list with two elements, <code>ticks</code> and <code>labels</code> . <code>ticks</code> must be a list with components <code>at</code> and <code>tck</code> which give the location and lengths of tick marks. <code>tck</code> can be a vector, and will be recycled to be as long as <code>at</code> . <code>labels</code> must be a list with components <code>at</code> , <code>labels</code> , and <code>check.overlap</code> . <code>at</code> and <code>labels</code> give the location and labels of the tick labels; this is usually the same as the location of the ticks, but is not required to be so. <code>check.overlap</code> is a logical flag indicating whether overlapping of labels should be avoided by omitting some of the labels while rendering. |

**top** This can be a logical flag; if TRUE, top is treated as being the same as bottom; if FALSE, axis annotation for the top axis is omitted. Alternatively, top can be a list like bottom.

Valid components in the return value of `yscale.components.default` are left and right. Their interpretations are analogous to (respectively) the bottom and top components described above.

### Examples

```
str(xscale.components.default(c(0, 1)))

set.seed(36872)
rln <- rlnorm(100)

densityplot(rln,
 scales = list(x = list(log = 2), alternating = 3),
 xlab = "Simulated lognormal variates",
 xscale.components = function(...) {
 ans <- xscale.components.default(...)
 ans$top <- ans$bottom
 ans$bottom$labels$labels <- parse(text = ans$bottom$labels$labels)
 anstoplabels$labels <-
 if (require(MASS))
 fractions(2^(anstoplabels$at))
 else
 2^(anstoplabels$at)
 ans
 })
}

Direct use of axis to show two temperature scales (Celcius and
Fahrenheit). This does not work for multi-row plots, and doesn't
do automatic allocation of space

F2C <- function(f) 5 * (f - 32) / 9
C2F <- function(c) 32 + 9 * c / 5

axis.CF <-
 function(side, ...)
{
 ylim <- current.panel.limits()$ylim
 switch(side,
 left = {
 prettyF <- pretty(ylim)
 labF <- parse(text = sprintf("%s ~ degree * F", prettyF))
 panel.axis(side = side, outside = TRUE,
 at = prettyF, labels = labF)
 },
 right = {
 prettyF <- pretty(ylim)
 labF <- parse(text = sprintf("%s ~ degree * F", prettyF))
 panel.axis(side = side, outside = TRUE,
 at = prettyF, labels = labF)
 }
)
}
```

```

right = {
 prettyC <- pretty(F2C(ylim))
 labC <- parse(text = sprintf("%s ~ degree * C", prettyC))
 panel.axis(side = side, outside = TRUE,
 at = C2F(prettyC), labels = labC)
},
axis.default(side = side, ...))
}

xyplot(nhtemp ~ time(nhtemp), aspect = "xy", type = "o",
 scales = list(y = list(alternating = 3)),
 axis = axis.CF, xlab = "Year", ylab = "Temperature",
 main = "Yearly temperature in New Haven, CT")

version using yscale.components

yscale.components.CF <-
 function(...)
{
 ans <- yscale.components.default(...)
 ans$right <- ans$left
 ans$left$labels$labels <-
 parse(text = sprintf("%s ~ degree * F", ans$left$labels$at))
 prettyC <- pretty(F2C(ans$num.limit))
 ans$right$ticks$at <- C2F(prettyC)
 ans$right$labels$at <- C2F(prettyC)
 ans$right$labels$labels <-
 parse(text = sprintf("%s ~ degree * C", prettyC))
 ans
}

xyplot(nhtemp ~ time(nhtemp), aspect = "xy", type = "o",
 scales = list(y = list(alternating = 3)),
 yscale.components = yscale.components.CF,
 xlab = "Year", ylab = "Temperature",
 main = "Yearly temperature in New Haven, CT")

```

G\_banking

*Banking***Description**

Calculates banking slope

**Usage**

```
banking(dx, dy)
```

**Arguments**

|        |                                         |
|--------|-----------------------------------------|
| dx, dy | vector of consecutive x, y differences. |
|--------|-----------------------------------------|

## Details

`banking` is the banking function used when `aspect = "xy"` in high level Trellis functions. It is usually not very meaningful except with `xyplot`. It considers the absolute slopes (based on `dx` and `dy`) and returns a value which when adjusted by the panel scale limits will make the median of the above absolute slopes correspond to a 45 degree line.

This function was inspired by the discussion of banking in the documentation for Trellis Graphics available at Bell Labs' website (see [Lattice](#)), but is most likely identical to an algorithm described by Cleveland et al (see below). It is not clear (to the author) whether this is the algorithm used in S-PLUS. Alternative banking rules, implemented as a similar function, can be used as a drop-in replacement by suitably modifying `lattice.options("banking")`.

## Examples

```
with and without banking

plot <- xyplot(sunspot.year ~ 1700:1988, xlab = "", type = "l",
 scales = list(x = list(alternating = 2)),
 main = "Yearly Sunspots")
print(plot, position = c(0, .3, 1, .9), more = TRUE)
print(update(plot, aspect = "xy", main = "", xlab = "Year"),
 position = c(0, 0, 1, .3))

cut-and-stack plot (see also xyplot.ts)

xyplot(sunspot.year ~ time(sunspot.year) | equal.count(time(sunspot.year)),
 xlab = "", type = "l", aspect = "xy", strip = FALSE,
 scales = list(x = list(alternating = 2, relation = "sliced")),
 as.table = TRUE, main = "Yearly Sunspots")
```

## Description

this function is used by high level Lattice functions like `xyplot` to parse the formula argument and evaluate various components of the data.

**Usage**

```
latticeParseFormula(model, data, dimension = 2,
 subset = TRUE, groups = NULL,
 multiple, outer,
 subscripts,
 drop)
```

**Arguments**

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| model           | the model/formula to be parsed. This can be in either of two possible forms, one for 2d and one for 3d formulas, determined by the dimension argument. The 2d formulas are of the form $y \sim x   g_1 * \dots * g_n$ , and the 3d formulas are of the form $z \sim x * y   g_1 * \dots * g_n$ . In the first form, $y$ may be omitted. The conditioning variables $g_1, \dots, g_n$ can be omitted in either case. |
| data            | the environment/dataset where the variables in the formula are evaluated.                                                                                                                                                                                                                                                                                                                                           |
| dimension       | dimension of the model, see above                                                                                                                                                                                                                                                                                                                                                                                   |
| subset          | index for choosing a subset of the data frame                                                                                                                                                                                                                                                                                                                                                                       |
| groups          | the grouping variable, if present                                                                                                                                                                                                                                                                                                                                                                                   |
| multiple, outer | logicals, determining how a '+' in the $y$ and $x$ components of the formula are processed. See <a href="#">xyplot</a> for details                                                                                                                                                                                                                                                                                  |
| subscripts      | logical, whether subscripts are to be calculated                                                                                                                                                                                                                                                                                                                                                                    |
| drop            | logical or list, similar to the drop.unused.levels argument in <a href="#">xyplot</a> , indicating whether unused levels of conditioning factors and data variables that are factors are to be dropped.                                                                                                                                                                                                             |

**Value**

returns a list with several components, including `left`, `right`, `left.name`, `right.name`, `condition` for 2-D, and `left`, `right.x`, `right.y`, `left.name`, `right.x.name`, `right.y.name`, `condition` for 3-D. Other possible components are `groups`, `subscr`

## Description

When a "trellis" object is plotted, panels are always drawn in an order such that columns vary the fastest, then rows and then pages. An optional function can be specified that determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. The function documented here implements the default behaviour, which is to match panel order with packet order, determined by varying the first conditioning variable the fastest, then the second, and so on. This matching is performed after any reordering and/or permutation of the conditioning variables.

## Usage

```
packet.panel.default(layout, condlevels, page, row, column,
 skip, all.pages.skip = TRUE)
```

## Arguments

- `layout` the layout argument in high level functions, suitably standardized.
- `condlevels` a list of levels of conditioning variables, after relevant permutations and/or re-ordering of levels
- `page, row, column` the location of the panel in the coordinate system of pages, rows and columns.
- `skip` the skip argument in high level functions
- `all.pages.skip` whether skip should be replicated over all pages. If FALSE, skip will be replicated to be only as long as the number of positions on a page, and that template will be used for all pages.

## Value

A suitable combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable. Specifically, if the return value is  $p$ , then the  $i$ -th conditioning variable will have level  $\text{condlevels}[[i]][p[i]]$ .

 packet.panel.default(layout = layout, page = n, ...)
 }
}
```

```

data(mtcars)
HP <- equal.count(mtcars$hp, 6)
p <-
 xyplot(mpg ~ disp | HP * factor(cyl),
 mtcars, layout = c(0, 6, 1))

print(p, packet.panel = packet.panel.page(1))
print(p, packet.panel = packet.panel.page(2))

```

**G\_panel.axis***Panel Function for Drawing Axis Ticks and Labels***Description**

`panel.axis` is the function used by lattice to draw axes. It is typically not used by users, except those wishing to create advanced annotation. Keep in mind issues of clipping when trying to use it as part of the panel function. `current.panel.limits` can be used to retrieve a panel's x and y limits.

**Usage**

```

panel.axis(side = c("bottom", "left", "top", "right"),
 at,
 labels = TRUE,
 draw.labels = TRUE,
 check.overlap = FALSE,
 outside = FALSE,
 ticks = TRUE,
 half = !outside,
 which.half,
 tck = as.numeric(ticks),
 rot = if (is.logical(labels)) 0 else c(90, 0),
 text.col, text.alpha, text.cex, text.font,
 text.fontfamily, text.fontface, text.lineheight,
 line.col, line.lty, line.lwd, line.alpha)

current.panel.limits(unit = "native")

```

**Arguments**

|                            |                                                                                                                                                                                                                                                          |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>side</code>          | A character string indicating which side axes are to be drawn on. Partial specification is allowed.                                                                                                                                                      |
| <code>at</code>            | Numeric vector giving location of labels.                                                                                                                                                                                                                |
| <code>labels</code>        | The labels to go along with <code>at</code> . The labels can be a character vector or a vector of expressions. Alternatively, <code>at</code> can be a logical flag: If TRUE, the labels are derived from <code>at</code> , otherwise, labels are empty. |
| <code>draw.labels</code>   | A logical indicating whether labels are to be drawn.                                                                                                                                                                                                     |
| <code>check.overlap</code> | A logical, whether to check for overlapping of labels. This also has the effect of removing <code>at</code> values that are 'too close' to the limits.                                                                                                   |

|                                                        |                                                                                                                                                                                                          |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>outside</code>                                   | A logical flag, indicating whether to draw the labels outside the panel or inside. Note that <code>outside=TRUE</code> will only have a visible effect if clipping is disabled for the viewport (panel). |
| <code>ticks</code>                                     | Logical flag, whether to draw the tickmarks.                                                                                                                                                             |
| <code>half</code>                                      | Logical flag, indicating whether only around half the scales will be drawn for each side. This is primarily used for axis labeling in <a href="#">splom</a> .                                            |
| <code>which.half</code>                                | Character string, either "lower" or "upper", indicating which half is to be used for tick locations if <code>half = TRUE</code> . Defaults to whichever is suitable for <a href="#">splom</a> .          |
| <code>tck</code>                                       | A numeric scalar multiplier for tick length. Can be negative, in which case the ticks point inwards.                                                                                                     |
| <code>rot</code>                                       | Rotation angle(s) for labels in degrees. Can be a vector of length 2 for x- and y-axes.                                                                                                                  |
| <code>text.col</code>                                  | Color for the axis label text. See <a href="#">gpar</a> for more details on this and the other graphical parameters listed below.                                                                        |
| <code>text.alpha</code>                                | Alpha-transparency value for the axis label text.                                                                                                                                                        |
| <code>text.cex</code>                                  | Size multiplier for the axis label text.                                                                                                                                                                 |
| <code>text.font, text.fontfamily, text.fontface</code> | Font for the axis label text.                                                                                                                                                                            |
| <code>text.lineheight</code>                           | Line height for the axis label text.                                                                                                                                                                     |
| <code>line.col</code>                                  | Color for the axis label text.                                                                                                                                                                           |
| <code>line.lty</code>                                  | Color for the axis.                                                                                                                                                                                      |
| <code>line.lwd</code>                                  | Color for the axis.                                                                                                                                                                                      |
| <code>line.alpha</code>                                | Alpha-transparency value for the axis.                                                                                                                                                                   |
| <code>unit</code>                                      | Which grid <a href="#">unit</a> the values should be in.                                                                                                                                                 |

## Details

`panel.axis` can draw axis tick marks inside or outside a panel (more precisely, a grid viewport). It honours the (native) axis scales. Used in [panel.pairs](#) for [splom](#), as well as for all the usual axis drawing by the print method for "trellis" objects. It can also be used to enhance plots 'after the fact' by adding axes.

## Value

`current.panel.limits` returns a list with components `xlim` and `ylim`, which are both numeric vectors of length 2, giving the scales of the current panel (viewport). The values correspond to the unit system specified by [unit](#), by default "native".

## Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

## Description

Control over lattice plots are provided through a collection of user specifiable functions that perform various tasks during the plotting. Not all information is available to all functions. The functions documented here attempt to provide a consistent interface to access relevant information from within these user specified functions, namely those specified as the `panel`, `strip` and `axis` functions.

## Usage

```
current.row(prefix)
current.column(prefix)
panel.number(prefix)
packet.number(prefix)
which.packet(prefix)

trellis.currentLayout(which = c("packet", "panel"), prefix)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>which</code>  | whether return value (a matrix) should contain panel numbers or packet numbers, which are usually, but not necessarily, the same (see below for details).                                                                                                              |
| <code>prefix</code> | A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See <a href="#">trellis.focus</a> . |

## Value

`trellis.currentLayout` returns a matrix with as many rows and columns as in the layout of panels in the current plot. Entries in the matrix are integer indices indicating which packet (or panel; see below) occupies that position, with 0 indicating the absence of a panel. `current.row` and `current.column` return integer indices specifying which row and column in the layout are currently active. `panel.number` returns an integer counting which panel is being drawn (starting from 1 for the first panel, a.k.a. the panel order). `packet.number` gives the packet number according to the packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. `which.packet` returns the combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable.

## Note

The availability of these functions make redundant some features available in earlier versions of lattice, namely optional arguments called `panel.number` and `packet.number` that were made available to `panel` and `strip`. If you have written such functions, it should be enough to replace instances of `panel.number` and `packet.number` by the corresponding function calls. You should also remove `panel.number` and `packet.number` from the argument list of your function to avoid a warning.

If these accessor functions are not enough for your needs, feel free to contact the maintainer and ask for more.

G\_Rows

*Extract rows from a list*

---

**Description**

Convenience function to extract subset of a list. Usually used in creating keys.

**Usage**

`Rows(x, which)`

**Arguments**

- |                    |                                                   |
|--------------------|---------------------------------------------------|
| <code>x</code>     | list with each member a vector of the same length |
| <code>which</code> | index for members of <code>x</code>               |

**Value**

A list similar to `x`, with each `x[[i]]` replaced by `x[[i]][which]`

## Description

These are (related to) the default panel functions for `cloud` and `wireframe`.

## Usage

```
ltransform3dMatrix(screen, R.mat)
ltransform3dto3d(x, R.mat, dist)
```

## Arguments

|        |                                                                         |
|--------|-------------------------------------------------------------------------|
| x      | x can be a numeric matrix with 3 rows for <code>ltransform3dto3d</code> |
| screen | list, as described in <a href="#">panel.cloud</a>                       |
| R.mat  | 4x4 transformation matrix in homogeneous coordinates                    |
| dist   | controls transformation to account for perspective viewing              |

## Details

`ltransform3dMatrix` and `ltransform3dto3d` are utility functions to help in computation of projections. These functions are used inside the panel functions for `cloud` and `wireframe`. They may be useful in user-defined panel functions as well.

The first function takes a list of the form of the `screen` argument in `cloud` and `wireframe` and a `R.mat`, a 4x4 transformation matrix in homogeneous coordinates, to return a new 4x4 transformation matrix that is the result of applying `R.mat` followed by the rotations in `screen`. The second function applies a 4x4 transformation matrix in homogeneous coordinates to a 3xn matrix representing points in 3-D space, and optionally does some perspective computations. (There has been no testing with non-trivial transformation matrices, and my knowledge of the homogeneous coordinate system is very limited, so there may be bugs here.)

**H\_barley***Yield data from a Minnesota barley trial*

---

**Description**

Total yield in bushels per acre for 10 varieties at 6 sites in each of two years.

**Usage**

`barley`

**Format**

A data frame with 120 observations on the following 4 variables.

**yield** Yield (averaged across three blocks) in bushels/acre.

**variety** Factor with levels "Svansota", "No. 462", "Manchuria", "No. 475", "Velvet", "Peatland", "Glabron", "No. 457", "Wisconsin No. 38", "Trebi".

**year** Factor with levels 1932, 1931

**site** Factor with 6 levels: "Grand Rapids", "Duluth", "University Farm", "Morris", "Crookston", "Waseca"

**Details**

These data are yields in bushels per acre, of 10 varieties of barley grown in 1/40 acre plots at University Farm, St. Paul, and at the five branch experiment stations located at Waseca, Morris, Crookston, Grand Rapids, and Duluth (all in Minnesota). The varieties were grown in three randomized blocks at each of the six stations during 1931 and 1932, different land being used each year of the test.

Immer et al. (1934) present the data for each Year\*Site\*Variety\*Block. The data here is the average yield across the three blocks.

Immer et al. (1934) refer (once) to the experiment as being conducted in 1930 and 1931, then later refer to it (repeatedly) as being conducted in 1931 and 1932. Later authors have continued the confusion.

Cleveland (1993) suggests that the data for the Morris site may have had the years switched.

H\_environmental

*Atmospheric environmental conditions in New York City*

---

### Description

Daily measurements of ozone concentration, wind speed, temperature and solar radiation in New York City from May to September of 1973.

### Usage

environmental

### Format

A data frame with 111 observations on the following 4 variables.

**ozone** Average ozone concentration (of hourly measurements) of in parts per billion.

**radiation** Solar radiation (from 08:00 to 12:00) in langleys.

**temperature** Maximum daily emperature in degrees Fahrenheit.

**wind** Average wind speed (at 07:00 and 10:00) in miles per hour.

 aspect=1,
 prepanel = function(x, y)
 prepanel.loess(x, y, span = 1),
 panel = function(x, y){
 panel.grid(h = 2, v = 2)
 panel.xyplot(x, y, cex = .5)
 panel.loess(x, y, span = 1)
 },
 xlab = "Solar radiation (langleyes)",
 ylab = "Ozone (cube root ppb)"
 detach()

Similar display using the coplot function
with(environmental,{
 coplot((ozone^.33) ~ radiation | temperature * wind,
 number=c(4,4),
 panel = function(x, y, ...) panel.smooth(x, y, span = .8, ...),
 xlab="Solar radiation (langleyes)",
 ylab="Ozone (cube root ppb)"
})
```

*H\_ethanol*

*Engine exhaust fumes from burning ethanol*

### Description

Ethanol fuel was burned in a single-cylinder engine. For various settings of the engine compression and equivalence ratio, the emissions of nitrogen oxides were recorded.

### Usage

`ethanol`

### Format

A data frame with 88 observations on the following 3 variables.

**NOx** Concentration of nitrogen oxides (NO and NO<sub>2</sub>) in micrograms/J.

**C** Compression ratio of the engine.

**E** Equivalence ratio—a measure of the richness of the air and ethanol fuel mixture.

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

Brinkman, N.D. (1981) Ethanol Fuel—A Single-Cylinder Engine Study of Efficiency and Exhaust Emissions. *SAE transactions*, **90**, 1410–1424.

**References**

**Examples**

```
Constructing panel functions on the fly
EE <- equal.count(ethanol$E, number=9, overlap=1/4)
xyplot(NOx ~ C | EE, data = ethanol,
 prepanel = function(x, y) prepanel.loess(x, y, span = 1),
 xlab = "Compression ratio", ylab = "NOx (micrograms/J)",
 panel = function(x, y) {
 panel.grid(h=-1, v= 2)
 panel.xyplot(x, y)
 panel.loess(x,y, span=1)
 },
 aspect = "xy")

Wireframe loess surface fit. See Figure 4.61 from Cleveland.
require(stats)
with(ethanol, {
 eth.lo <- loess(NOx ~ C * E, span = 1/3, parametric = "C",
 drop.square = "C", family="symmetric")
 eth.marginal <- list(C = seq(min(C), max(C), length.out = 25),
 E = seq(min(E), max(E), length.out = 25))
 eth.grid <- expand.grid(eth.marginal)
 eth.fit <- predict(eth.lo, eth.grid)
 wireframe(eth.fit ~ eth.grid$C * eth.grid$E,
 shade=TRUE,
 screen = list(z = 40, x = -60, y=0),
 distance = .1,
 xlab = "C", ylab = "E", zlab = "NOx")
})
```

**Description**

These data from the Connecticut Tumor Registry present age-adjusted numbers of melanoma skin-cancer incidences per 100,000 people in Connecticut for the years from 1936 to 1972.

**Usage**

`melanoma`

### Format

A data frame with 37 observations on the following 2 variables.

**year** Years 1936 to 1972.

**incidence** Rate of melanoma cancer per 100,000 population.

### Note

This dataset is not related to the `melanoma` dataset in the **boot** package with the same name.

The S-PLUS 6.2 help for the melanoma data says that the incidence rate is per *million*, but this is not consistent with data found at the National Cancer Institute (<http://www.nci.nih.gov>).

### Examples

```
Time-series plot. Figure 3.64 from Cleveland.
xyplot(incidence ~ year,
 data = melanoma,
 aspect = "xy",
 panel = function(x, y)
 panel.xyplot(x, y, type="o", pch = 16),
 ylim = c(0, 6),
 xlab = "Year",
 ylab = "Incidence")
```

*H\_singer*

*Heights of New York Choral Society singers*

### Description

Heights in inches of the singers in the New York Choral Society in 1979. The data are grouped according to voice part. The vocal range for each voice part increases in pitch according to the following order: Bass 2, Bass 1, Tenor 2, Tenor 1, Alto 2, Alto 1, Soprano 2, Soprano 1.

### Usage

`singer`

## Format

A data frame with 235 observations on the following 2 variables.

**height** Height in inches of the singers.

**voice.part** (Unordered) factor with levels "Bass 2", "Bass 1", "Tenor 2", "Tenor 1", "Alto 2", "Alto 1", "Soprano 2", "Soprano 1".

## Examples

```
Separate histogram for each voice part (Figure 1.2 from Cleveland)
histogram(~ height | voice.part,
 data = singer,
 aspect=1,
 layout = c(2, 4),
 nint=15,
 xlab = "Height (inches)")

Quantile-Quantile plot (Figure 2.11 from Cleveland)
qqmath(~ height | voice.part,
 data=singer,
 aspect=1,
 layout=c(2,4),
 prepanel = prepanel.qqmathline,
 panel = function(x, ...) {
 panel.grid()
 panel.qqmathline(x, ...)
 panel.qqmath(x, ...)
 },
 xlab = "Unit Normal Quantile",
 ylab="Height (inches)")
```

## Description

A (hopefully) simpler alternative to `trellis.par.get/set`. This is deprecated, and the same functionality is now available with `trellis.par.set`

**Usage**

```
lset(theme = col.whitebg())
```

**Arguments**

theme a list describing how to change the settings of the current active device. Valid components are those in the list returned by `trellis.par.get()`. Each component must itself be a list, with one or more of the appropriate components (need not have all components). Changes are made to the settings for the currently active device only.

# Chapter 24

## The mgcv package

---

`mgcv`-package

*Mixed GAM Computation Vehicle with GCV/AIC/REML smoothness estimation and GAMMs by REML/PQL*

---

### Description

`mgcv` provides functions for generalized additive modelling (`gam` and `bam`) and generalized additive mixed modelling (`gamm`, and `random.effects`). The term GAM is taken to include any GLM estimated by quadratically penalized (possibly quasi-) likelihood maximization.

Particular features of the package are facilities for automatic smoothness selection, and the provision of a variety of smooths of more than one variable. User defined smooths can be added. A Bayesian approach to confidence/credible interval calculation is provided. Linear functionals of smooths, penalization of parametric model terms and linkage of smoothing parameters are all supported. Lower level routines for generalized ridge regression and penalized linearly constrained least squares are also available.

### Details

`mgcv` provides generalized additive modelling functions `gam`, `predict.gam` and `plot.gam`, which are very similar in use to the S functions of the same name designed by Trevor Hastie (with some extensions). However the underlying representation and estimation of the models is based on a penalized regression spline approach, with automatic smoothness selection. A number of other functions such as `summary.gam` and `anova.gam` are also provided, for extracting information from a fitted `gamObject`.

Use of `gam` is much like use of `glm`, except that within a `gam` model formula, isotropic smooths of any number of predictors can be specified using `s` terms, while scale invariant smooths of any number of predictors can be specified using `te` terms. `smooth.terms` provides an overview of the built in smooth classes, and `random.effects` should be referred to for an overview of random effects terms (see also `mrf` for Markov random fields). Estimation is by penalized likelihood or quasi-likelihood maximization, with smoothness selection by GCV, GACV, gAIC/UBRE or (RE)ML. See `gam`, `gam.models`, `linear.functional.terms` and `gam.selection` for some discussion of model specification and selection. For detailed control of fitting see `gam.convergence`, `gam` arguments `method` and `optimizer` and `gam.control`. For checking and visualization see `gam.check`, `choose.k`, `vis.gam` and `plot.gam`. While a number of types of smoother are built into the package, it is also extendable with user defined smooths, see `smooth.construct`, for example.

A Bayesian approach to smooth modelling is used to derive standard errors on predictions, and hence credible intervals. The Bayesian covariance matrix for the model coefficients is returned in `Vp` of the `gamObject`. See `predict.gam` for examples of how this can be used to obtain credible regions for any quantity derived from the fitted model, either directly, or by direct simulation from the posterior distribution of the model coefficients. Approximate p-values can also be obtained for testing individual smooth terms for equality to the zero function, using similar ideas. Frequentist approximations can be used for hypothesis testing based model comparison. See `anova.gam` and `summary.gam` for more on hypothesis testing.

For large datasets (that is large `n`) see `bam` which is a version of `gam` with a much reduced memory footprint.

The package also provides a generalized additive mixed modelling function, `gamm`, based on a PQL approach and `lme` from the `nlme` library (for an `lme4` based version, see package `gamm4`). `gamm` is particularly useful for modelling correlated data (i.e. where a simple independence model for the residual variation is inappropriate). In addition, low level routine `magic` can fit models to data with a known correlation structure.

Some underlying GAM fitting methods are available as low level fitting functions: see `magic`. But there is little functionality that can not be more conveniently accessed via `gam`. Penalized weighted least squares with linear equality and inequality constraints is provided by `pcls`.

For a complete list of functions type `library(help=mgcv)`. See also [mgcv-FAQ](#).

## Examples

```
see examples for gam and gamm
```

## Description

Performs hypothesis tests relating to one or more fitted `gam` objects. For a single fitted `gam` object, Wald tests of the significance of each parametric and smooth term are performed, so interpretation is analogous to `drop1` rather than `anova.lm` (i.e. it's like type III ANOVA, rather than a sequential type I ANOVA). Otherwise the fitted models are compared using an analysis of deviance table: this latter approach should not be used to test the significance of terms which can be penalized to zero. See details.

## Usage

```
S3 method for class 'gam'
anova(object, ..., dispersion = NULL, test = NULL,
 freq = FALSE, p.type=0)
S3 method for class 'anova.gam'
print(x, digits = max(3, getOption("digits") - 3), ...)
```

## Arguments

|                          |                                                                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>object, ...</code> | fitted model objects of class <code>gam</code> as produced by <code>gam()</code> .                                            |
| <code>x</code>           | an <code>anova.gam</code> object produced by a single model call to <code>anova.gam()</code> .                                |
| <code>dispersion</code>  | a value for the dispersion parameter: not normally used.                                                                      |
| <code>test</code>        | what sort of test to perform for a multi-model call. One of "Chisq", "F" or "Cp".                                             |
| <code>freq</code>        | whether to use frequentist or Bayesian approximations for parametric term p-values. See <code>summary.gam</code> for details. |
| <code>p.type</code>      | selects exact test statistic to use for single smooth term p-values. See <code>summary.gam</code> for details.                |
| <code>digits</code>      | number of digits to use when printing output.                                                                                 |

## Details

If more than one fitted model is provided than `anova.glm` is used, with the difference in model degrees of freedom being taken as the difference in effective degrees of freedom. The p-values resulting from this are only approximate, and must be used with care. The approximation is most accurate when the comparison relates to unpenalized terms, or smoothers with a null space of dimension greater than zero. (Basically we require that the difference terms could be well approximated by unpenalized terms with degrees of freedom approximately the effective degrees of freedom). In simulations the p-values are usually slightly too low. For terms with a zero-dimensional null space (i.e. those which can be penalized to zero) the approximation is often very poor, and significance can be greatly overstated: i.e. p-values are often substantially too low. This case applies to random effect terms.

Note also that in the multi-model call to `anova.gam`, it is quite possible for a model with more terms to end up with lower effective degrees of freedom, but better fit, than the notionally null model with fewer terms. In such cases it is very rare that it makes sense to perform any sort of test, since there is then no basis on which to accept the notional null model.

If only one model is provided then the significance of each model term is assessed using Wald tests, conditional on the smoothing parameter estimates: see `summary.gam` and Wood (in press) for details. The p-values provided here are better justified than in the multi model case, and have close to the correct distribution under the null, unless smoothing parameters are poorly identified. ML or REML smoothing parameter selection leads to the best results in simulations as they tend to

avoid occasional severe undersmoothing. In replication of the full simulation study of Scheipl et al. (2008) the tests give almost indistinguishable power to the method recommended there, but slightly too low p-values under the null in their section 3.1.8 test for a smooth interaction (the Scheipl et al. recommendation is not used directly, because it only applies in the Gaussian case, and requires model refits, but it is available in package RLRsim).

In the single model case `print.anova.gam` is used as the printing method.

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (`freq=TRUE`), since the parametric terms themselves are usually unpenalized. Default P-values for parameteric terms that are penalized using the `paraPen` argument will not be good.

### Value

In the multi-model case `anova.gam` produces output identical to `anova.glm`, which it in fact uses.

In the single model case an object of class `anova.gam` is produced, which is in fact an object returned from `summary.gam`.

`print.anova.gam` simply produces tabulated output.

### WARNING

If models 'a' and 'b' differ only in terms with no un-penalized components then p values from `anova(a,b)` are unreliable, and usually much too low.

Default P-values will usually be wrong for parametric terms penalized using 'paraPen': use `freq=TRUE` to obtain better p-values when the penalties are full rank and represent conventional random effects.

For a single model, interpretation is similar to `drop1`, not `anova.lm`.

### Author(s)

### Examples

```
library(mgcv)
set.seed(0)
dat <- gamSim(5,n=200,scale=2)

b<-gam(y ~ x0 + s(x1) + s(x2) + s(x3),data=dat)
anova(b)
```

```
b1<-gam(y ~ x0 + s(x1) + s(x2),data=dat)
anova(b,b1,test="F")
```

bam

*Generalized additive models for very large datasets*

## Description

Fits a generalized additive model (GAM) to a very large data set, the term ‘GAM’ being taken to include any quadratically penalized GLM. The degree of smoothness of model terms is estimated as part of fitting. In use the function is much like [gam](#), except that the numerical methods are designed for datasets containing upwards of several tens of thousands of data. The advantage of [bam](#) is much lower memory footprint than [gam](#), but it can also be much faster, for large datasets. [bam](#) can also compute on a cluster set up by the [parallel](#) package.

## Usage

```
bam(formula,family=gaussian(),data=list(),weights=NULL,subset=NULL,
 na.action=na.omit, offset=NULL,method="fREML",control=list(),
 scale=0,gamma=1,knots=NULL,sp=NULL,min.sp=NULL,paraPen=NULL,
 chunk.size=10000,rho=0,sparse=FALSE,cluster=NULL,gc.level=1,
 use.chol=FALSE,samfrac=1,...)
```

## Arguments

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>formula</b>   | A GAM formula (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). This is exactly like the formula for a GLM except that smooth terms, <b>s</b> and <b>te</b> can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).                                                                                                                 |
| <b>family</b>    | This is a family object specifying the distribution and link to use in fitting etc. See <a href="#">glm</a> and <a href="#">family</a> for more details. A negative binomial family is provided: see <a href="#">negbin</a> , but only the known theta case is supported by <a href="#">bam</a> .                                                                                                                                                      |
| <b>data</b>      | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <a href="#">environment(formula)</a> : typically the environment from which <a href="#">gam</a> is called.                                                                                                                                                                                                 |
| <b>weights</b>   | prior weights on the data.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>subset</b>    | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                                                                                              |
| <b>na.action</b> | a function which indicates what should happen when the data contain ‘NA’s. The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is unset. The “factory-fresh” default is ‘na.omit’.                                                                                                                                                                                                                                    |
| <b>offset</b>    | Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in <b>formula</b> : this conforms to the behaviour of <a href="#">lm</a> and <a href="#">glm</a> .                                                                                                                                                                                         |
| <b>method</b>    | The smoothing parameter estimation method. “GCV.Cp” to use GCV for unknown scale parameter and Mallows’ Cp/UBRE/AIC for known scale. “GACV.Cp” is equivalent, but using GACV in place of GCV. “REML” for REML estimation, including of unknown scale, “P-REML” for REML estimation, but using a Pearson estimate of the scale. “ML” and “P-ML” are similar, but using maximum likelihood in place of REML. Default “fREML” uses fast REML computation. |

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| control    | A list of fit control parameters to replace defaults returned by <a href="#">gam.control</a> . Any control parameters not supplied stay at their default values.                                                                                                                                                                                                                                                                                                       |
| scale      | If this is positive then it is taken as the known scale parameter. Negative signals that the scale paraemter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.                                                                                                                                                     |
| gamma      | It is sometimes useful to inflate the model degrees of freedom in the GCV or UBRE/AIC score by a constant multiplier. This allows such a multiplier to be supplied.                                                                                                                                                                                                                                                                                                    |
| knots      | this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the k value supplied (note that the number of knots is not always just k). See <a href="#">tprs</a> for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.                                                |
| sp         | A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters.                                |
| min.sp     | Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters <code>full.sp</code> , in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. <code>length(min.sp)</code> should always be the same as the total number of penalties (so it may be longer than <code>sp</code> , if smooths share smoothing parameters). |
| paraPen    | optional list specifying any penalties to be applied to parametric model terms. <a href="#">gam.models</a> explains more.                                                                                                                                                                                                                                                                                                                                              |
| chunk.size | The model matrix is created in chunks of this size, rather than ever being formed whole.                                                                                                                                                                                                                                                                                                                                                                               |
| rho        | An AR1 error model can be used for the residuals (based on dataframe order), of Gaussian-identity link models. This is the AR1 correlation parameter.                                                                                                                                                                                                                                                                                                                  |
| sparse     | If all smooths are P-splines and all tensor products are of the form <code>te(...,bs="ps",np=FALSE)</code> then in principle computation could be made faster using sparse matrix methods, and you could set this to TRUE. In practice the speed up is disappointing, and the computation is less well conditioned than the default. See details.                                                                                                                      |
| cluster    | <code>bam</code> can compute the computationally dominant QR decomposition in parallel using <a href="#">parLapply</a> from the <code>parallel</code> package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code.                                                                                                                                                              |
| gc.level   | to keep the memory footprint down, it helps to call the garbage collector often, but this takes a substatial amount of time. Setting this to zero means that garbage collection only happens when R decides it should. Setting to 2 gives frequent garbage collection. 1 is in between.                                                                                                                                                                                |
| use.chol   | By default <code>bam</code> uses a very stable QR update approach to obtaining the QR decomposition of the model matrix. For well conditioned models an alternative accumulates the crossproduct of the model matrix and then finds its Choleski decomposition, at the end. This is somewhat more efficient, computationally.                                                                                                                                          |

|         |                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| samfrac | For very large sample size Generalized additive models the number of iterations needed for the model fit can be reduced by first fitting a model to a random sample of the data, and using the results to supply starting values. This initial fit is run with sloppy convergence tolerances, so is typically very low cost. <code>samfrac</code> is the sampling fraction to use. 0.1 is often reasonable. |
| ...     | further arguments for passing on e.g. to <code>gam.fit</code> (such as <code>mustart</code> ).                                                                                                                                                                                                                                                                                                              |

## Details

`bam` operates by first setting up the basis characteristics for the smooths, using a representative subsample of the data. Then the model matrix is constructed in blocks using [predict.gam](#). For each block the factor R, from the QR decomposition of the whole model matrix is updated, along with Q'y, and the sum of squares of y. At the end of block processing, fitting takes place, without the need to ever form the whole model matrix.

In the generalized case, the same trick is used with the weighted model matrix and weighted pseudodata, at each step of the PIRLS. Smoothness selection is performed on the working model at each stage (performance oriented iteration), to maintain the small memory footprint. This is trivial to justify in the case of GCV or Cp/UBRE/AIC based model selection, and for REML/ML is justified via the asymptotic multivariate normality of Q'z where z is the IRLS pseudodata.

Note that POI is not as stable as the default nested iteration used with [gam](#), but that for very large, information rich, datasets, this is unlikely to matter much.

Note also that it is possible to spend most of the computational time on basis evaluation, if an expensive basis is used. In practice this means that the default "tp" basis should be avoided: almost any other basis (e.g. "cr" or "ps") can be used in the 1D case, and tensor product smooths (te) are typically much less costly in the multi-dimensional case.

If `cluster` is provided as a cluster set up using [makeCluster](#) (or [makeForkCluster](#)) from the `parallel` package, then the rate limiting QR decomposition of the model matrix is performed in parallel using this cluster. Note that the speed ups are often not that great. On a multi-core machine it is usually best to set the cluster size to the number of physical cores, which is often less than what is reported by [detectCores](#). Using more than the number of physical cores can result in no speed up at all (or even a slow down). Note that a highly parallel BLAS may negate all advantage from using a cluster of cores. Computing in parallel of course requires more memory than computing in series. See examples.

If the argument `sparse=TRUE` then QR updating is replaced by an alternative scheme, in which the model matrix is stored whole as a sparse matrix. This only makes sense if all smooths are P-splines and all tensor products are of the form `te(...,bs="ps",np=FALSE)`, but no check is made. The computations are then based on the Choleski decomposition of the crossproduct of the sparse model matrix. Although this crossproduct is nearly dense, sparsity should make its formation efficient, which is useful as it is the leading order term in the operations count. However there is no benefit in using sparse methods to form the Choleski decomposition, given that the crossproduct is dense. In practice the sparse matrix handling overheads mean that modest or no speed ups are produced by this approach, while the computation is less stable than the default, and the memory footprint often higher (but please let the author know if you find an example where the speedup is really worthwhile).

## Value

An object of class "gam" as described in [gamObject](#).

## WARNINGS

The routine will be slow if the default "tp" basis is used.

You must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

This routine is less stable than 'gam' for the same dataset.

The negbin family is only supported for the \*known theta\* case.

## Examples

```
library(mgcv)
Some not very large examples...

dat <- gamSim(1,n=40000,dist="normal",scale=20)
bs <- "cr";k <- 20
b <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+s(x3,bs=bs,k=k),data=dat)
summary(b)
plot(b,pages=1,rug=FALSE) ## plot smooths, but not rug
plot(b,pages=1,rug=FALSE,seWithMean=TRUE) ## 'with intercept' CIs

ba <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+s(x3,bs=bs,k=k),data=dat,method="GCV.Cp") ## use GCV
summary(ba)

A Poisson example...

k <- 15
dat <- gamSim(1,n=15000,dist="poisson",scale=.1)
system.time(b1 <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+s(x3,bs=bs,k=k),data=dat,family=poisson()))
b1

repeat on a cluster (need much larger n to be worthwhile!)
require(parallel)
nc <- 2 ## cluster size, set for example portability
if (detectCores()>1) { ## no point otherwise
 cl <- makeCluster(nc)
 ## could also use makeForkCluster, but read warnings first!
} else cl <- NULL
```

```

system.time(b2 <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+

 s(x3,bs=bs,k=k),data=dat,family=poisson(),cluster=c1))

... first call has startup overheads, repeat shows speed up...

system.time(b2 <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+

 s(x3,bs=bs,k=k),data=dat,family=poisson(),cluster=c1))

fv <- predict(b2,cluster=c1) ## parallel prediction

if (!is.null(cl)) stopCluster(cl)

b2

Sparse smoother example...

dat <- gamSim(1,n=10000,dist="poisson",scale=.1)

system.time(b3 <- bam(y ~ te(x0,x1,bs="ps",k=10,np=FALSE)+

 s(x2,bs="ps",k=30)+s(x3,bs="ps",k=30),data=dat,

 method="REML",family=poisson(),sparse=TRUE))

b3

```

**bam.update***Update a strictly additive bam model for new data.***Description**

Gaussian with identity link models fitted by [bam](#) can be efficiently updated as new data becomes available, by simply updateing the QR decomposition on which estimation is based, and re-optimizing the smoothing parameters, starting from the previous estimates. This routine implements this.

**Usage**

```
bam.update(b,data,chunk.size=10000)
```

**Arguments**

- |                   |                                                                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>b</b>          | A <code>gam</code> object fitted by <a href="#">bam</a> and representing a strictly additive model (i.e. gaussian errors, identity link).  |
| <b>data</b>       | Extra data to augment the original data used to obtain <code>b</code> . Must include a column of weights if the original fit was weighted. |
| <b>chunk.size</b> | size of subsets of data to process in one go when getting fitted values.                                                                   |

**Details**

`bam.update` updates the QR decomposition of the (weighted) model matrix of the GAM represented by `b` to take account of the new data. The orthogonal factor multiplied by the response vector is also updated. Given these updates the model and smoothing parameters can be re-estimated, as if the whole dataset (original and the new data) had been fitted in one go. The function will use the same AR1 model for the residuals as that employed in the original model fit (see `rho` parameter of [bam](#)).

Note that there may be small numerical differences in fit between fitting the data all at once, and fitting in stages by updating, if the smoothing bases used have any of their details set with reference to the data (e.g. default knot locations).

dat0 <- dat[1:(n-1000),]
method <- "ML"

b <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+s(x3,bs=bs,k=k),data=dat0,method=method,rho=0.7)
```

```
b1 <- bam.update(b,dat1)

summary(b1);summary(b2);summary(b3)
```

## choose.k

*Basis dimension choice for smooths***Description**

Choosing the basis dimension, and checking the choice, when using penalized regression smoothers.

Penalized regression smoothers gain computational efficiency by virtue of being defined using a basis of relatively modest size,  $k$ . When setting up models in the `mgcv` package, using `s` or `te` terms in a model formula,  $k$  must be chosen: the defaults are essentially arbitrary.

In practice  $k-1$  (or  $k$ ) sets the upper limit on the degrees of freedom associated with an `s` smooth (1 degree of freedom is usually lost to the identifiability constraint on the smooth). For `te` smooths the upper limit of the degrees of freedom is given by the product of the  $k$  values provided for each marginal smooth less one, for the constraint. However the actual effective degrees of freedom are controlled by the degree of penalization selected during fitting, by GCV, AIC, REML or whatever is specified. The exception to this is if a smooth is specified using the `fx=TRUE` option, in which case it is unpenalized.

So, exact choice of  $k$  is not generally critical: it should be chosen to be large enough that you are reasonably sure of having enough degrees of freedom to represent the underlying ‘truth’ reasonably well, but small enough to maintain reasonable computational efficiency. Clearly ‘large’ and ‘small’ are dependent on the particular problem being addressed.

As with all model assumptions, it is useful to be able to check the choice of  $k$  informally. If the effective degrees of freedom for a model term are estimated to be much less than  $k-1$  then this is unlikely to be very worthwhile, but as the EDF approach  $k-1$ , checking can be important. A useful general purpose approach goes as follows: (i) fit your model and extract the deviance residuals; (ii) for each smooth term in your model, fit an equivalent, single, smooth to the residuals, using a substantially increased  $k$  to see if there is pattern in the residuals that could potentially be explained by increasing  $k$ . Examples are provided below.

The obvious, but more costly, alternative is simply to increase the suspect  $k$  and refit the original model. If there are no statistically important changes as a result of doing this, then  $k$  was large enough. (Change in the smoothness selection criterion, and/or the effective degrees of freedom, when  $k$  is increased, provide the obvious numerical measures for whether the fit has changed substantially.)

`gam.check` runs a simple simulation based check on the basis dimensions, which can help to flag up terms for which  $k$  is too low. Grossly too small  $k$  will also be visible from partial residuals available with `plot.gam`.

One scenario that can cause confusion is this: a model is fitted with  $k=10$  for a smooth term, and the EDF for the term is estimated as 7.6, some way below the maximum of 9. The model is then refitted with  $k=20$  and the EDF increases to 8.7 - what is happening - how come the EDF was not 8.7 the first time around? The explanation is that the function space with  $k=20$  contains a larger subspace of functions with EDF 8.7 than did the function space with  $k=10$ : one of the functions in this larger subspace fits the data a little better than did any function in the smaller subspace. These subtleties seldom have much impact on the statistical conclusions to be drawn from a model fit, however.

**Examples**

```
Simulate some data
library(mgcv)
set.seed(1)
dat <- gamSim(1,n=400,scale=2)

fit a GAM with quite low 'k'
b<-gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),data=dat)
plot(b,pages=1,residuals=TRUE) ## hint of a problem in s(x2)

the following suggests a problem with s(x2)
gam.check(b)

Another approach (see below for more obvious method)....
check for residual pattern, removeable by increasing 'k'
typically 'k', below, should be substantially larger than
the original, 'k' but certainly less than n/2.
Note use of cheap "cs" shrinkage smoothers, and gamma=1.4
to reduce chance of overfitting...
rsd <- residuals(b)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x2,k=40,bs="cs"),gamma=1.4,data=dat) ## 'k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

refit...
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=20)+s(x3,k=6),data=dat)
gam.check(b) ## better

similar example with multi-dimensional smooth
b1 <- gam(y~s(x0)+s(x1,x2,k=15)+s(x3),data=dat)
rsd <- residuals(b1)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,x2,k=100,bs="ts"),gamma=1.4,data=dat) ## 'k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

gam.check(b1) ## shows same problem

and a 'te' example
b2 <- gam(y~s(x0)+te(x1,x2,k=4)+s(x3),data=dat)
rsd <- residuals(b2)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~te(x1,x2,k=10,bs="cs"),gamma=1.4,data=dat) ## 'k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

gam.check(b2) ## shows same problem
```

```

same approach works with other families in the original model
dat <- gamSim(1,n=400,scale=.25,dist="poisson")
bp<-gam(y~s(x0,k=5)+s(x1,k=5)+s(x2,k=5)+s(x3,k=5),
 family=poisson,data=dat,method="ML")

gam.check(bp)

rsd <- residuals(bp)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x2,k=40,bs="cs"),gamma=1.4,data=dat) ## 'k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

rm(dat)

More obvious, but more expensive tactic... Just increase
suspicious k until fit is stable.

set.seed(0)
dat <- gamSim(1,n=400,scale=2)
fit a GAM with quite low 'k'
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),
 data=dat,method="REML")
b
edf for 3rd smooth is highest as proportion of k -- increase k
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=12)+s(x3,k=6),
 data=dat,method="REML")
b
edf substantially up, -ve REML substantially down
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=24)+s(x3,k=6),
 data=dat,method="REML")
b
slight edf increase and -ve REML change
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=40)+s(x3,k=6),
 data=dat,method="REML")
b
definitely stabilized (but really k around 20 would have been fine)

```

columb

*Reduced version of Columbus OH crime data*

## Description

By district crime data from Columbus OH, together with polygons describing district shape. Useful for illustrating use of simple Markov Random Field smoothers.

## Usage

```

data(columb)
data(columb.polys)

```

## Format

`columb` is a 49 row data frame with the following columns

**area** land area of district

**home.value** housing value in 1000USD.

**income** household income in 1000USD.

**crime** residential burglaries and auto thefts per 1000 households.

**open.space** measure of open space in district.

**district** code identifying district, and matching names(`columb.polys`).

`columb.polys` contains the polygons defining the areas in the format described below.

## Details

The data frame `columb` relates to the districts whose boundaries are coded in `columb.polys`. `columb.polys[[i]]` is a 2 column matrix, containing the vertices of the polygons defining the boundary of the *i*th district. `columb.polys[[2]]` has an artificial hole inserted to illustrate how holes in districts can be specified. Different polygons defining the boundary of a district are separated by NA rows in `columb.polys[[1]]`, and a polygon enclosed within another is treated as a hole in that region (a hole should never come first). `names(columb.polys)` matches `columb$district` (order unimportant).

## Source

The data are adapted from the `columbus` example in the `spdep` package, where the original source is given as:

Anselin, Luc. 1988. Spatial econometrics: methods and models. Dordrecht: Kluwer Academic, Table 12.1 p. 189.

## Examples

```

`concurvity`

*GAM concurvity measures*

## Description

Produces summary measures of concurvity between `gam` components.

## Usage

```
concurvity(b, full=TRUE)
```

## Arguments

- |                   |                                                                                                                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>b</code>    | An object inheriting from class "gam".                                                                                                                                                                                |
| <code>full</code> | If TRUE then concurvity of each term with the whole of the rest of the model is considered. If FALSE then pairwise concurvity measures between each smooth term (as well as the parametric component) are considered. |

## Details

Concurvity occurs when some smooth term in a model could be approximated by one or more of the other smooth terms in the model. This is often the case when a smooth of space is included in a model, along with smooths of other covariates that also vary more or less smoothly in space. Similarly it tends to be an issue in models including a smooth of time, along with smooths of other time varying covariates.

Concurvity can be viewed as a generalization of co-linearity, and causes similar problems of interpretation. It can also make estimates somewhat unstable (so that they become sensitive to apparently innocuous modelling details, for example).

This routine computes three related indices of concurvity, all bounded between 0 and 1, with 0 indicating no problem, and 1 indicating total lack of identifiability. The three indices are all based on the idea that a smooth term,  $f$ , in the model can be decomposed into a part,  $g$ , that lies entirely in the space of one or more other terms in the model, and a remainder part that is completely within the term's own space. If  $g$  makes up a large part of  $f$  then there is a concurvity problem. The indices used are all based on the square of  $\|g\|/\|f\|$ , that is the ratio of the squared Euclidean norms of the vectors of  $f$  and  $g$  evaluated at the observed covariate values.

The three measures are as follows

**worst** This is the largest value that the square of  $\|g\|/\|f\|$  could take for any coefficient vector. This is a fairly pessimistic measure, as it looks at the worst case irrespective of data. This is the only measure that is symmetric.

**observed** This just returns the value of the square of  $\|g\|/\|f\|$  according to the estimated coefficients. This could be a bit over-optimistic about the potential for a problem in some cases.

**estimate** This is the squared F-norm of the basis for  $g$  divided by the F-norm of the basis for  $f$ . It is a measure of the extent to which the  $f$  basis can be explained by the  $g$  basis. It does not suffer from the pessimism or potential for over-optimism of the previous two measures, but is less easy to understand.

## Value

If `full=TRUE` a matrix with one column for each term and one row for each of the 3 concurvity measures detailed below. If `full=FALSE` a list of 3 matrices, one for each of the three concurvity measures detailed below. Each row of the matrix relates to how the model terms depend on the model term supplying that rows name.

## Examples

```
library(mgcv)
simulate data with concurvity...
set.seed(8);n<- 200
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
 (10 * x)^3 * (1 - x)^10
t <- sort(runif(n)) ## first covariate
make covariate x a smooth function of t + noise...
```

```

x <- f2(t) + rnorm(n)*3
simulate response dependent on t and x...
y <- sin(4*pi*t) + exp(x/20) + rnorm(n)*.3

fit model...
b <- gam(y ~ s(t,k=15) + s(x,k=15),method="REML")

assess concurvity between each term and 'rest of model'...
concurvity(b)

... and now look at pairwise concurvity between terms...
concurvity(b,full=FALSE)

```

**cSplineDes***Evaluate cyclic B spline basis***Description**

Uses `splineDesign` to set up the model matrix for a cyclic B-spline basis.

**Usage**

```
cSplineDes(x, knots, ord = 4)
```

**Arguments**

- |                    |                                                                   |
|--------------------|-------------------------------------------------------------------|
| <code>x</code>     | covariate values for smooth.                                      |
| <code>knots</code> | The knot locations: the range of these must include all the data. |
| <code>ord</code>   | order of the basis. 4 is a cubic spline basis. Must be >1.        |

**Details**

The routine is a wrapper that sets up a B-spline basis, where the basis functions wrap at the first and last knot locations.

**Value**

A matrix with `length(x)` rows and `length(knots)-1` columns.

## Examples

```

require(mgcv)
create some x's and knots...
n <- 200
x <- 0:(n-1)/(n-1);k<- 0:5/5
X <- cSplineDes(x,k) ## cyclic spline design matrix
plot evaluated basis functions...
plot(x,X[,1],type="l"); for (i in 2:5) lines(x,X[,i],col=i)
check that the ends match up....
ee <- X[1,]-X[n,];ee
tol <- .Machine$double.eps^.75
if (all.equal(ee,ee*0,tol=tol)!=TRUE)
 stop("cyclic spline ends don't match!")

similar with uneven data spacing...
x <- sort(runif(n)) + 1 ## sorting just makes end checking easy
k <- seq(min(x),max(x),length=8) ## create knots
X <- cSplineDes(x,k) ## get cyclic spline model matrix
plot(x,X[,1],type="l"); for (i in 2:ncol(X)) lines(x,X[,i],col=i)
ee <- X[1,]-X[n,];ee ## do ends match??
tol <- .Machine$double.eps^.75
if (all.equal(ee,ee*0,tol=tol)!=TRUE)
 stop("cyclic spline ends don't match!")

```

**exclude.too.far**

*Exclude prediction grid points too far from data*

## Description

Takes two arrays defining the nodes of a grid over a 2D covariate space and two arrays defining the location of data in that space, and returns a logical vector with elements TRUE if the corresponding node is too far from data and FALSE otherwise. Basically a service routine for `vis.gam` and `plot.gam`.

## Usage

```
exclude.too.far(g1,g2,d1,d2,dist)
```

## Arguments

|                   |                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>g1</code>   | co-ordinates of grid relative to first axis.                                                                                                                                  |
| <code>g2</code>   | co-ordinates of grid relative to second axis.                                                                                                                                 |
| <code>d1</code>   | co-ordinates of data relative to first axis.                                                                                                                                  |
| <code>d2</code>   | co-ordinates of data relative to second axis.                                                                                                                                 |
| <code>dist</code> | how far away counts as too far. Grid and data are first scaled so that the grid lies exactly in the unit square, and <code>dist</code> is a distance within this unit square. |

## Details

Linear scalings of the axes are first determined so that the grid defined by the nodes in g1 and g2 lies exactly in the unit square (i.e. on [0,1] by [0,1]). These scalings are applied to g1, g2, d1 and d2. The minimum Euclidean distance from each node to a datum is then determined and if it is greater than dist the corresponding entry in the returned array is set to TRUE (otherwise to FALSE). The distance calculations are performed in compiled code for speed without storage overheads.

## Value

A logical array with TRUE indicating a node in the grid defined by g1, g2 that is ‘too far’ from any datum.

plot(gx[!tf],gy[!tf],pch=".");points(x,y,col=2)
```

`extract.lme.cov`

*Extract the data covariance matrix from an lme object*

## Description

This is a service routine for [gamm](#). Extracts the estimated covariance matrix of the data from an `lme` object, allowing the user control about which levels of random effects to include in this calculation. `extract.lme.cov` forms the full matrix explicitly: `extract.lme.cov2` tries to be more economical than this.

## Usage

```
extract.lme.cov(b,data,start.level=1)
extract.lme.cov2(b,data,start.level=1)
```

### Arguments

|                          |                                                                                                                                                                                                                     |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>b</code>           | A fitted model object returned by a call to <code>lme</code> .                                                                                                                                                      |
| <code>data</code>        | The data frame/ model frame that was supplied to <code>lme</code> .                                                                                                                                                 |
| <code>start.level</code> | The level of nesting at which to start including random effects in the calculation. This is used to allow smooth terms to be estimated as random effects, but treated like fixed effects for variance calculations. |

### Details

The random effects, correlation structure and variance structure used for a linear mixed model combine to imply a covariance matrix for the response data being modelled. These routines extracts that covariance matrix. The process is slightly complicated, because different components of the fitted model object are stored in different orders (see function code for details!).

The `extract.lme.cov` calculation is not optimally efficient, since it forms the full matrix, which may in fact be sparse. `extract.lme.cov2` is more efficient. If the covariance matrix is diagonal, then only the leading diagonal is returned; if it can be written as a block diagonal matrix (under some permutation of the original data) then a list of matrices defining the non-zero blocks is returned along with an index indicating which row of the original data each row/column of the block diagonal matrix relates to. The block sizes are defined by the coarsest level of grouping in the random effect structure.

`gamm` uses `extract.lme.cov2`.

`extract.lme.cov` does not currently deal with the situation in which the grouping factors for a correlation structure are finer than those for the random effects. `extract.lme.cov2` does deal with this situation.

### Value

For `extract.lme.cov` an estimated covariance matrix.

For `extract.lme.cov2` a list containing the estimated covariance matrix and an indexing array. The covariance matrix is stored as the elements on the leading diagonal, a list of the matrices defining a block diagonal matrix, or a full matrix if the previous two options are not possible.

```

**fix.family.link**

*Modify families for use in GAM fitting and checking*

**Description**

Generalized Additive Model fitting by ‘outer’ iteration, requires extra derivatives of the variance and link functions to be added to family objects. The first 3 functions add what is needed. Model checking can be aided by adding quantile and random deviate generating functions to the family. The final two functions do this.

**Usage**

```
fix.family.link(fam)
fix.family.var(fam)
fix.family.ls(fam)
fix.family.qf(fam)
fix.family.rd(fam)
```

**Arguments**

**fam**                  A family.

**Details**

Consider the first 3 function first.

Outer iteration GAM estimation requires derivatives of the GCV, UBRE/gAIC, GACV, REML or ML score, which are obtained by finding the derivatives of the model coefficients w.r.t. the log smoothing parameters, using the implicit function theorem. The expressions for the derivatives require the second and third derivatives of the link w.r.t. the mean (and the 4th derivatives if Fisher scoring is not used). Also required are the first and second derivatives of the variance function w.r.t. the mean (plus the third derivative if Fisher scoring is not used). Finally REML or ML estimation of smoothing parameters requires the log saturated likelihood and its first two derivatives w.r.t. the scale parameter. These functions add functions evaluating these quantities to a family.

If the family already has functions dvar, d2var, d3var, d2link, d3link, d4link and for RE/ML ls, then these functions simply return the family unmodified: this allows non-standard links to be used with [gam](#) when using outer iteration (performance iteration operates with unmodified families). Note that if you only need Fisher scoring then d4link and d3var can be dummy, as they are ignored. similalry ls is only needed for RE/ML.

The dvar function is a function of a mean vector, mu, and returns a vector of corresponding first derivatives of the family variance function. The d2link function is also a function of a vector

of mean values,  $\mu$ : it returns a vector of second derivatives of the link, evaluated at  $\mu$ . Higher derivatives are defined similarly.

If modifying your own family, note that you can often get away with supplying only a `dvar` and `d2var`, function if your family only requires links that occur in one of the standard families.

The second two functions are useful for investigating the distribution of residuals and are used by `qq.gam`. If possible the functions add quantile (`qf`) or random deviate (`rd`) generating functions to the family. If a family already has `qf` or `rd` functions then it is left unmodified. `qf` functions are only available for some families, and for quasi families neither type of function is available.

### Value

A family object with extra component functions `dvar`, `d2var`, `d2link`, `d3link`, `d4link`, `ls`, and possibly `qf` and `rd`, depending on which functions are called.

`fixDependence`

*Detect linear dependencies of one matrix on another*

### Description

Identifies columns of a matrix  $X_2$  which are linearly dependent on columns of a matrix  $X_1$ . Primarily of use in setting up identifiability constraints for nested GAMs.

### Usage

```
fixDependence(X1, X2, tol=.Machine$double.eps^.5, rank.def=0, strict=FALSE)
```

### Arguments

|                       |                                                                                                                                                                                                                      |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>X1</code>       | A matrix.                                                                                                                                                                                                            |
| <code>X2</code>       | A matrix, the columns of which may be partially linearly dependent on the columns of $X_1$ .                                                                                                                         |
| <code>tol</code>      | The tolerance to use when assessing linear dependence.                                                                                                                                                               |
| <code>rank.def</code> | If the degree of rank deficiency in $X_2$ , given $X_1$ , is known, then it can be supplied here, and <code>tol</code> is then ignored. Unused unless positive and not greater than the number of columns in $X_2$ . |
| <code>strict</code>   | if TRUE then only columns individually dependent on $X_1$ are detected, if FALSE then enough columns to make the reduced $X_2$ full rank and independent of $X_1$ are detected.                                      |

### Details

The algorithm uses a simple approach based on QR decomposition: see Wood (2006, section 4.10.2) for details.

**Value**

A vector of the columns of X2 which are linearly dependent on columns of X1 (or which need to be deleted to achieve independence and full rank if `strict==FALSE`). NULL if the two matrices are independent.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

**References**

**Examples**

```
library(mgcv)
n<-20;c1<-4;c2<-7
X1<-matrix(runif(n*c1),n,c1)
X2<-matrix(runif(n*c2),n,c2)
X2[,3]<-X1[,2]+X2[,4]*.1
X2[,5]<-X1[,1]*.2+X1[,2]*.04
fixDependence(X1,X2)
fixDependence(X1,X2,strict=TRUE)
```

*formula.gam*

*GAM formula*

**Description**

Description of `gam` formula (see Details), and how to extract it from a fitted `gam` object.

**Usage**

```
S3 method for class 'gam'
formula(x,...)
```

**Arguments**

|                |                                                                                                                     |
|----------------|---------------------------------------------------------------------------------------------------------------------|
| <code>x</code> | fitted model objects of class <code>gam</code> (see <a href="#">gamObject</a> ) as produced by <code>gam()</code> . |
| ...            | un-used in this case                                                                                                |

**Details**

The formula supplied to `gam` is exactly like that supplied to `glm` except that smooth terms, `s` and `te` can be added to the right hand side (and `.` is not supported in `gam` formulae).

Smooth terms are specified by expressions of the form:

`s(x1,x2,...,k=12,fx=FALSE,bs="tp",by=z,id=1)`

where `x1`, `x2`, etc. are the covariates which the smooth is a function of, and `k` is the dimension of the basis used to represent the smooth term. If `k` is not specified then basis specific defaults are used. Note that these defaults are essentially arbitrary, and it is important to check that they are not

so small that they cause oversmoothing (too large just slows down computation). Sometimes the modelling context suggests sensible values for k, but if not informal checking is easy: see [choose.k](#) and [gam.check](#).

fx is used to indicate whether or not this term should be unpenalized, and therefore have a fixed number of degrees of freedom set by k (almost always k-1). bs indicates the basis to use for the smooth: the built in options are described in [smooth.terms](#), and user defined smooths can be added (see [user.defined.smooth](#)). If bs is not supplied then the default "tp" ([tprs](#)) basis is used. by can be used to specify a variable by which the smooth should be multiplied. For example `gam(y~s(x,by=z))` would specify a model  $E(y) = f(x)z$  where  $f(\cdot)$  is a smooth function. The by option is particularly useful for models in which different functions of the same variable are required for each level of a factor and for ‘varying coefficient models’: see [gam.models](#). id is used to give smooths identities: smooths with the same identity have the same basis, penalty and smoothing parameter (but different coefficients, so they are different functions).

An alternative for specifying smooths of more than one covariate is e.g.:

```
te(x,z,bs=c("tp","tp"),m=c(2,3),k=c(5,10))
```

which would specify a tensor product smooth of the two covariates x and z constructed from marginal t.p.r.s. bases of dimension 5 and 10 with marginal penalties of order 2 and 3. Any combination of basis types is possible, as is any number of covariates. [te](#) provides further information.

Both s and te terms accept an sp argument of supplied smoothing parameters: positive values are taken as fixed values to be used, negative to indicate that the parameter should be estimated. If sp is supplied then it over-rides whatever is in the sp argument to `gam`, if it is not supplied then it defaults to all negative, but does not over-ride the sp argument to `gam`.

Formulae can involve nested or “overlapping” terms such as

$y \sim s(x) + s(z) + s(x, z)$  or  $y \sim s(x, z) + s(z, v)$ :

see [gam.side](#) for further details and examples.

Smooth terms in a `gam` formula will accept matrix arguments as covariates (and corresponding by variable), in which case a ‘summation convention’ is invoked. Consider the example of `s(X, Z, by=L)` where X, Z and L are n by m matrices. Let F be the n by m matrix that results from evaluating the smooth at the values in X and Z. Then the contribution to the linear predictor from the term will be `rowSums(F*L)` (note the element-wise multiplication). This convention allows the linear predictor of the GAM to depend on (a discrete approximation to) any linear functional of a smooth: see [linear.functional.terms](#) for more information and examples (including functional linear models/signal regression).

Note that `gam` allows any term in the model formula to be penalized (possibly by multiple penalties), via the paraPen argument. See [gam.models](#) for details and example code.

## Value

Returns the model formula, `x$formula`. Provided so that anova methods print an appropriate description of the model.

**formXtViX***Form component of GAMM covariance matrix***Description**

This is a service routine for **gamm**. Given,  $V$ , an estimated covariance matrix obtained using **extract.lme.cov2** this routine forms  $X^T V^{-1} X$  as efficiently as possible, given the structure of  $V$  (usually sparse).

**Usage**

```
formXtViX(V, X)
```

**Arguments**

- |          |                                                                     |
|----------|---------------------------------------------------------------------|
| <b>V</b> | A data covariance matrix list returned from <b>extract.lme.cov2</b> |
| <b>X</b> | A model matrix.                                                     |

**Details**

The covariance matrix returned by **extract.lme.cov2** may be in a packed and re-ordered format, since it is usually sparse. Hence a special service routine is required to form the required products involving this matrix.

**Value**

A matrix.

**fs.test***FELSPLINE test function*

---

## Description

Implements a finite area test function based on one proposed by Tim Ramsay (2002).

## Usage

```
fs.test(x,y,r0=.1,r=.5,l=3,b=1,exclude=TRUE)
fs.boundary(r0=.1,r=.5,l=3,n.theta=20)
```

## Arguments

|         |                                                                                                                           |
|---------|---------------------------------------------------------------------------------------------------------------------------|
| x,y     | Points at which to evaluate the test function.                                                                            |
| r0      | The test domain is a sort of bent sausage. This is the radius of the inner bend                                           |
| r       | The radius of the curve at the centre of the sausage.                                                                     |
| l       | The length of an arm of the sausage.                                                                                      |
| b       | The rate at which the function increases per unit increase in distance along the centre line of the sausage.              |
| exclude | Should exterior points be set to NA?                                                                                      |
| n.theta | How many points to use in a piecewise linear representation of a quarter of a circle, when generating the boundary curve. |

## Details

The function details are not given in the source article: but this is pretty close. The function is modified from Ramsay (2002), in that it bulges, rather than being flat: this makes a better test of the smoother.

## Value

`fs.test` returns function evaluations, or NAs for points outside the boundary. `fs.boundary` returns a list of `x,y` points to be jointed up in order to define/draw the boundary.

## Examples

```
require(mgcv)
plot the function, and its boundary...
fsb <- fs.boundary()
m<-300;n<-150
xm <- seq(-1,4,length=m);yn<-seq(-1,1,length=n)
xx <- rep(xm,n);yy<-rep(yn,rep(m,n))
tru <- matrix(fs.test(xx,yy),m,n) ## truth
image(xm,yn,tru,col=heat.colors(100),xlab="x",ylab="y")
lines(fsbx,fsby,lwd=3)
contour(xm,yn,tru,levels=seq(-5,5,by=.25),add=TRUE)
```

**full.score**

*GCV/UBRE score for use within nlm*

## Description

Evaluates GCV/UBRE score for a GAM, given smoothing parameters. The routine calls [gam.fit](#) to fit the model, and is usually called by [nlm](#) to optimize the smoothing parameters.

This is basically a service routine for [gam](#), and is not usually called directly by users. It is only used in this context for GAMs fitted by outer iteration (see [gam.outer](#)) when the the outer method is "[nlm.fd](#)" (see [gam](#) argument optimizer).

## Usage

```
full.score(sp,G,family,control,gamma,...)
```

## Arguments

|                      |                                                                        |
|----------------------|------------------------------------------------------------------------|
| <code>sp</code>      | The logs of the smoothing parameters                                   |
| <code>G</code>       | a list returned by <code>mgcv:::gam.setup</code>                       |
| <code>family</code>  | The family object for the GAM.                                         |
| <code>control</code> | a list returned be <a href="#">gam.control</a>                         |
| <code>gamma</code>   | the degrees of freedom inflation factor (usually 1).                   |
| <code>...</code>     | other arguments, typically for passing on to <a href="#">gam.fit</a> . |

## Value

The value of the GCV/UBRE score, with attribute "full.gam.object" which is the full object returned by [gam.fit](#).

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

## Description

Fits a generalized additive model (GAM) to data, the term ‘GAM’ being taken to include any quadratically penalized GLM. The degree of smoothness of model terms is estimated as part of fitting. `gam` can also fit any GLM subject to multiple quadratic penalties (including estimation of degree of penalization). Isotropic or scale invariant smooths of any number of variables are available as model terms, as are linear functionals of such smooths; confidence/credible intervals are readily available for any quantity predicted using a fitted model; `gam` is extendable: users can add smooths.

Smooth terms are represented using penalized regression splines (or similar smoothers) with smoothing parameters selected by GCV/UBRE/AIC/REML or by regression splines with fixed degrees of freedom (mixtures of the two are permitted). Multi-dimensional smooths are available using penalized thin plate regression splines (isotropic) or tensor product splines (when an isotropic smooth is inappropriate). For an overview of the smooths available see [smooth.terms](#). For more on specifying models see [gam.models](#), [random.effects](#) and [linear.functional.terms](#). For more on model selection see [gam.selection](#). Do read [gam.check](#) and [choose.k](#).

See `gam` from package `gam`, for GAMs via the original Hastie and Tibshirani approach (see details for differences to this implementation).

For very large datasets see `bam`, for mixed GAM see `gamm` and `random.effects`.

## Usage

```
gam(formula,family=gaussian(),data=list(),weights=NULL,subset=NULL,
na.action,offset=NULL,method="GCV.Cp",
optimizer=c("outer","newton"),control=list(),scale=0,
select=FALSE,knots=NULL,sp=NULL,min.sp=NULL,H=NULL,gamma=1,
fit=TRUE,paraPen=NULL,G=NULL,in.out,...)
```

## Arguments

- |                      |                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code> | A GAM formula (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). This is exactly like the formula for a GLM except that smooth terms, <code>s</code> and <code>te</code> can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).                                      |
| <code>family</code>  | This is a family object specifying the distribution and link to use in fitting etc. See <a href="#">glm</a> and <a href="#">family</a> for more details. A negative binomial family is provided: see <a href="#">negbin</a> . quasi families actually result in the use of extended quasi-likelihood if <code>method</code> is set to a RE/ML method (McCullagh and Nelder, 1989, 9.6). |
| <code>data</code>    | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>gam</code> is called.                                                                                                                                        |
| <code>weights</code> | prior weights on the data.                                                                                                                                                                                                                                                                                                                                                              |
| <code>subset</code>  | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                               |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| na.action | a function which indicates what should happen when the data contain ‘NA’s. The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is unset. The “factory-fresh” default is ‘na.omit’.                                                                                                                                                                                                                                                  |
| offset    | Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in formula: this conforms to the behaviour of lm and glm.                                                                                                                                                                                                                                                |
| control   | A list of fit control parameters to replace defaults returned by <a href="#">gam.control</a> . Values not set assume default values.                                                                                                                                                                                                                                                                                                                                 |
| method    | The smoothing parameter estimation method. “GCV.Cp” to use GCV for unknown scale parameter and Mallows’ Cp/UBRE/AIC for known scale. “GACV.Cp” is equivalent, but using GACV in place of GCV. “REML” for REML estimation, including of unknown scale, “P-REML” for REML estimation, but using a Pearson estimate of the scale. “ML” and “P-ML” are similar, but using maximum likelihood in place of REML.                                                           |
| optimizer | An array specifying the numerical optimization method to use to optimize the smoothing parameter estimation criterion (given by method). “perf” for performance iteration. “outer” for the more stable direct approach. “outer” can use several alternative optimizers, specified in the second element of optimizer: “newton” (default), “bfgs”, “optim”, “nlm” and “nls.fitter” (the latter is based entirely on finite differenced derivatives and is very slow). |
| scale     | If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.                                                                                                                                                   |
| select    | If this is TRUE then gam can add an extra penalty to each term so that it can be penalized to zero. This means that the smoothing parameter estimation that is part of fitting can completely remove terms from the model. If the corresponding smoothing parameter is estimated as zero then the extra penalty has no effect.                                                                                                                                       |
| knots     | this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the k value supplied (note that the number of knots is not always just k). See <a href="#">tp</a> for what happens in the “tp”/“ts” case. Different terms can use different numbers of knots, unless they share a covariate.                                                |
| sp        | A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then length(sp) must correspond to the number of underlying smoothing parameters.                                           |
| min.sp    | Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters full.sp, in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. length(min.sp) should always be the same as the total number of penalties (so it may be longer than sp, if smooths share smoothing parameters).                                        |
| H         | A user supplied fixed quadratic penalty on the parameters of the GAM can be supplied, with this as its coefficient matrix. A common use of this term is to add a ridge penalty to the parameters of the GAM in circumstances in which the model is close to un-identifiable on the scale of the linear predictor, but perfectly well defined on the response scale.                                                                                                  |

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| gamma   | It is sometimes useful to inflate the model degrees of freedom in the GCV or UBRE/AIC score by a constant multiplier. This allows such a multiplier to be supplied.                                                                                                                                                                                                                                                                                                                         |
| fit     | If this argument is TRUE then gam sets up the model and fits it, but if it is FALSE then the model is set up and an object G containing what would be required to fit is returned. See argument G.                                                                                                                                                                                                                                                                                          |
| paraPen | optional list specifying any penalties to be applied to parametric model terms. <a href="#">gam.models</a> explains more.                                                                                                                                                                                                                                                                                                                                                                   |
| G       | Usually NULL, but may contain the object returned by a previous call to gam with fit=FALSE, in which case all other arguments are ignored except for gamma, in.out, scale, control, method optimizer and fit.                                                                                                                                                                                                                                                                               |
| in.out  | optional list for initializing outer iteration. If supplied then this must contain two elements: sp should be an array of initialization values for all smoothing parameters (there must be a value for all smoothing parameters, whether fixed or to be estimated, but those for fixed s.p.s are not used); scale is the typical scale of the GCV/UBRE function, for passing to the outer optimizer, or the the initial value of the scale parameter, if this is to be estimated by RE/ML. |
| ...     | further arguments for passing on e.g. to gam.fit (such as mustart).                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Details

A generalized additive model (GAM) is a generalized linear model (GLM) in which the linear predictor is given by a user specified sum of smooth functions of the covariates plus a conventional parametric component of the linear predictor. A simple example is:

$$\log(E(y_i)) = f_1(x_{1i}) + f_2(x_{2i})$$

where the (independent) response variables  $y_i \sim \text{Poi}$ , and  $f_1$  and  $f_2$  are smooth functions of covariates  $x_1$  and  $x_2$ . The log is an example of a link function.

If absolutely any smooth functions were allowed in model fitting then maximum likelihood estimation of such models would invariably result in complex overfitting estimates of  $f_1$  and  $f_2$ . For this reason the models are usually fit by penalized likelihood maximization, in which the model (negative log) likelihood is modified by the addition of a penalty for each smooth function, penalizing its ‘wiggleness’. To control the tradeoff between penalizing wiggleness and penalizing badness of fit each penalty is multiplied by an associated smoothing parameter: how to estimate these parameters, and how to practically represent the smooth functions are the main statistical questions introduced by moving from GLMs to GAMs.

The mgcv implementation of gam represents the smooth functions using penalized regression splines, and by default uses basis functions for these splines that are designed to be optimal, given the number basis functions used. The smooth terms can be functions of any number of covariates and the user has some control over how smoothness of the functions is measured.

gam in mgcv solves the smoothing parameter estimation problem by using the Generalized Cross Validation (GCV) criterion

$$nD/(n - DoF)^2$$

or an Un-Biased Risk Estimator (UBRE) criterion

$$D/n + 2sDoF/n - s$$

where  $D$  is the deviance,  $n$  the number of data,  $s$  the scale parameter and  $DoF$  the effective degrees of freedom of the model. Notice that UBRE is effectively just AIC rescaled, but is only used when  $s$  is known.

Alternatives are GACV, or a Laplace approximation to REML. There is some evidence that the latter may actually be the most effective choice.

Smoothing parameters are chosen to minimize the GCV, UBRE/AIC, GACV or REML scores for the model, and the main computational challenge solved by the `mgcv` package is to do this efficiently and reliably. Various alternative numerical methods are provided which can be set by argument `optimizer`.

Broadly `gam` works by first constructing basis functions and one or more quadratic penalty coefficient matrices for each smooth term in the model formula, obtaining a model matrix for the strictly parametric part of the model formula, and combining these to obtain a complete model matrix (/design matrix) and a set of penalty matrices for the smooth terms. Some linear identifiability constraints are also obtained at this point. The model is fit using `gam.fit`, a modification of `glm.fit`. The GAM penalized likelihood maximization problem is solved by Penalized Iteratively Reweighted Least Squares (P-IRLS) (see e.g. Wood 2000). Smoothing parameter selection is integrated in one of two ways. (i) ‘Performance iteration’ uses the fact that at each P-IRLS iteration a penalized weighted least squares problem is solved, and the smoothing parameters of that problem can be estimated by GCV or UBRE. Eventually, in most cases, both model parameter estimates and smoothing parameter estimates converge. (ii) Alternatively the P-IRLS scheme is iterated to convergence for each trial set of smoothing parameters, and GCV, UBRE or REML scores are only evaluated on convergence - optimization is then ‘outer’ to the P-IRLS loop: in this case the P-IRLS iteration has to be differentiated, to facilitate optimization, and `gam.fit3` is used in place of `gam.fit`. The default is the second method, outer iteration.

Several alternative basis-penalty types are built in for representing model smooths, but alternatives can easily be added (see `smooth.terms` for an overview and `smooth.construct` for how to add smooth classes). In practice the default basis is usually the best choice, but the choice of the basis dimension (`k` in the `s` and `te` terms) is something that should be considered carefully (the exact value is not critical, but it is important not to make it restrictively small, nor very large and computationally costly). The basis should be chosen to be larger than is believed to be necessary to approximate the smooth function concerned. The effective degrees of freedom for the smooth will then be controlled by the smoothing penalty on the term, and (usually) selected automatically (with an upper limit set by `k-1` or occasionally `k`). Of course the `k` should not be made too large, or computation will be slow (or in extreme cases there will be more coefficients to estimate than there are data).

Note that `gam` assumes a very inclusive definition of what counts as a GAM: basically any penalized GLM can be used: to this end `gam` allows the non smooth model components to be penalized via argument `paraPen` and allows the linear predictor to depend on general linear functionals of smooths, via the summation convention mechanism described in `linear.functional.terms`.

Details of the default underlying fitting methods are given in Wood (2011 and 2004). Some alternative methods are discussed in Wood (2000 and 2006).

`gam()` is not a clone of Trevor Hastie’s original (as supplied in S-PLUS or package `gam`) The major differences are (i) that by default estimation of the degree of smoothness of model terms is part of model fitting, (ii) a Bayesian approach to variance estimation is employed that makes for easier confidence interval calculation (with good coverage probabilities), (iii) that the model can depend on any (bounded) linear functional of smooth terms, (iv) the parametric part of the model can be penalized, (v) simple random effects can be incorporated, and (vi) the facilities for incorporating smooths of more than one variable are different: specifically there are no `lo` smooths, but instead (a) `s` terms can have more than one argument, implying an isotropic smooth and (b) `te` or `t2` smooths are provided as an effective means for modelling smooth interactions of any number of variables via scale invariant tensor product smooths. Splines on the sphere, Duchon splines and Gaussian Markov Random Fields are also available. See `gam` from package `gam`, for GAMs via the original Hastie and Tibshirani approach.

**Value**

If `fit=FALSE` the function returns a list `G` of items needed to fit a GAM, but doesn't actually fit it. Otherwise the function returns an object of class "gam" as described in [gamObject](#).

**WARNINGS**

The default basis dimensions used for smooth terms are essentially arbitrary, and it should be checked that they are not too small. See [choose.k](#) and [gam.check](#).

You must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

Automatic smoothing parameter selection is not likely to work well when fitting models to very few response data.

For data with many zeroes clustered together in the covariate space it is quite easy to set up GAMs which suffer from identifiability problems, particularly when using Poisson or binomial families. The problem is that with e.g. log or logit links, mean value zero corresponds to an infinite range on the linear predictor scale.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

Front end design inspired by the S function of the same name based on the work of Hastie and Tibshirani (1990). Underlying methods owe much to the work of Wahba (e.g. 1990) and Gu (e.g. 2002).

```

**gam.check***Some diagnostics for a fitted gam model***Description**

Takes a fitted `gam` object produced by `gam()` and produces some diagnostic information about the fitting procedure and results. The default is to produce 4 residual plots, some information about the convergence of the smoothness selection optimization, and to run diagnostic tests of whether the basis dimension choices are adequate.

**Usage**

```
gam.check(b, old.style=FALSE,
 type=c("deviance", "pearson", "response"),
 k.sample=5000, k.rep=200,
 rep=0, level=.9, rl.col=2, rep.col="gray80", ...)
```

**Arguments**

- |                                          |                                                                                            |
|------------------------------------------|--------------------------------------------------------------------------------------------|
| <code>b</code>                           | a fitted <code>gam</code> object as produced by <code>gam()</code> .                       |
| <code>old.style</code>                   | If you want old fashioned plots, exactly as in Wood, 2006, set to TRUE.                    |
| <code>type</code>                        | type of residuals, see <code>residuals.gam</code> , used in all plots.                     |
| <code>k.sample</code>                    | Above this k testing uses a random sub-sample of data.                                     |
| <code>k.rep</code>                       | how many re-shuffles to do to get p-value for k testing.                                   |
| <code>rep, level, rl.col, rep.col</code> | arguments passed to <code>qq.gam()</code> when <code>old.style</code> is false, see there. |
| <code>...</code>                         | extra graphics parameters to pass to plotting functions.                                   |

## Details

Checking a fitted `gam` is like checking a fitted `glm`, with two main differences. Firstly, the basis dimensions used for smooth terms need to be checked, to ensure that they are not so small that they force oversmoothing: the defaults are arbitrary. `choose.k` provides more detail, but the diagnostic tests described below and reported by this function may also help. Secondly, fitting may not always be as robust to violation of the distributional assumptions as would be the case for a regular GLM, so slightly more care may be needed here. In particular, the theory of quasi-likelihood implies that if the mean variance relationship is OK for a GLM, then other departures from the assumed distribution are not problematic: GAMs can sometimes be more sensitive. For example, un-modelled overdispersion will typically lead to overfit, as the smoothness selection criterion tries to reduce the scale parameter to the one specified. Similarly, it is not clear how sensitive REML and ML smoothness selection will be to deviations from the assumed response distribution. For these reasons this routine uses an enhanced residual QQ plot.

This function plots 4 standard diagnostic plots, some smoothing parameter estimation convergence information and the results of tests which may indicate if the smoothing basis dimension for a term is too low.

Usually the 4 plots are various residual plots. For the default optimization methods the convergence information is summarized in a readable way, but for other optimization methods, whatever is returned by way of convergence diagnostics is simply printed.

The test of whether the basis dimension for a smooth is adequate is based on computing an estimate of the residual variance based on differencing residuals that are near neighbours according to the (numeric) covariates of the smooth. This estimate divided by the residual variance is the k-index reported. The further below 1 this is, the more likely it is that there is missed pattern left in the residuals. The p-value is computed by simulation: the residuals are randomly re-shuffled `k.rep` times to obtain the null distribution of the differencing variance estimator, if there is no pattern in the residuals. For models fitted to more than `k.sample` data, the tests are based of `k.sample` randomly sampled data. Low p-values may indicate that the basis dimension, `k`, has been set too low, especially if the reported edf is close to  $k'$ , the maximum possible EDF for the term. Note the disconcerting fact that if the test statistic itself is based on random resampling and the null is true, then the associated p-values will of course vary widely from one replicate to the next. Currently smooths of factor variables are not supported and will give an NA p-value.

Doubling a suspect `k` and re-fitting is sensible: if the reported edf increases substantially then you may have been missing something in the first fit. Of course p-values can be low for reasons other than a too low `k`. See `choose.k` for fuller discussion.

The QQ plot produced is usually created by a call to `qq.gam`, and plots deviance residuals against approximate theoretical quantiles of the deviance residual distribution, according to the fitted model. If this looks odd then investigate further using `qq.gam`. Note that residuals for models fitted to binary data contain very little information useful for model checking (it is necessary to find some way of aggregating them first), so the QQ plot is unlikely to be useful in this case.

## Value

A vector of reference quantiles for the residual distribution, if these can be computed.

## Examples

```
library(mgcv)
set.seed(0)
dat <- gamSim(1,n=200)
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat)
plot(b,pages=1)
gam.check(b,pch=19,cex=.3)
```

*gam.control*

*Setting GAM fitting defaults*

## Description

This is an internal function of package `mgcv` which allows control of the numerical options for fitting a GAM. Typically users will want to modify the defaults if model fitting fails to converge, or if the warnings are generated which suggest a loss of numerical stability during fitting. To change the default choice of fitting method, see [gam](#) arguments `method` and `optimizer`.

## Usage

```
gam.control(irls.reg=0.0,epsilon = 1e-06, maxit = 100,
 mgcv.tol=1e-7,mgcv.half=15, trace = FALSE,
 rank.tol=.Machine$double.eps^0.5,
 nlm=list(),optim=list(),newton=list(),
 outerPIsteps=0,idLinksBases=TRUE,scalePenalty=TRUE,
 keepData=FALSE)
```

## Arguments

|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>irls.reg</code> | For most models this should be 0. The iteratively re-weighted least squares method by which GAMs are fitted can fail to converge in some circumstances. For example, data with many zeroes can cause problems in a model with a log link, because a mean of zero corresponds to an infinite range of linear predictor values. Such convergence problems are caused by a fundamental lack of identifiability, but do not show up as lack of identifiability in the penalized linear model problems that have to be solved at each stage of iteration. In such circumstances it is possible to apply a ridge regression penalty to the model to impose identifiability, and <code>irls.reg</code> is the size of the penalty. |

| newton       | list of control parameters to pass to default Newton optimizer used for outer estimation of log smoothing parameters. See details.                                                                                                                                                                                              |
| outerPIsteps | The number of performance interation steps used to initialize outer iteration.                                                                                                                                                                                                                                                  |
| idLinksBases | If smooth terms have their smoothing parameters linked via the <code>id</code> mechanism (see <code>s</code> ), should they also have the same bases. Set this to FALSE only if you are sure you know what you are doing (you should almost surely set <code>scalePenalty</code> to FALSE as well in this case).                |
| scalePenalty | <code>gamm</code> is somewhat sensitive to the absolute scaling of the penalty matrices of a smooth relative to its model matrix. This option rescales the penalty matrices to accomodate this problem. Probably should be set to FALSE if you are linking smoothing parameters but have set <code>idLinkBases</code> to FALSE. |
| keepData     | Should a copy of the original data argument be kept in the <code>gam</code> object? Strict compatibility with class <code>glm</code> would keep it, but it wastes space to do so.                                                                                                                                               |

## Details

Outer iteration using `newton` is controlled by the list `newton` with the following elements: `conv.tol` (default 1e-6) is the relative convergence tolerance; `maxNstep` is the maximum length allowed for an element of the Newton search direction (default 5); `maxSstep` is the maximum length allowed for an element of the steepest descent direction (only used if Newton fails - default 2); `maxHalf` is the maximum number of step halvings to permit before giving up (default 30).

If outer iteration using `nlm` is used for fitting, then the control list `nlm` stores control arguments for calls to routine `nlm`. The list has the following named elements: (i) `ndigit` is the number of significant digits in the GCV/UBRE score - by default this is worked out from `epsilon`; (ii) `gradtol` is the tolerance used to judge convergence of the gradient of the GCV/UBRE score to zero - by default set to  $10 * \text{epsilon}$ ; (iii) `stepmax` is the maximum allowable log smoothing parameter step - defaults to 2; (iv) `steptol` is the minimum allowable step length - defaults to 1e-4; (v) `iterlim` is the maximum number of optimization steps allowed - defaults to 200; (vi) `check.analyticals` indicates whether the built in exact derivative calculations should be checked numerically - defaults to FALSE. Any of these which are not supplied and named in the list are set to their default values.

Outer iteration using `optim` is controlled using list `optim`, which currently has one element: `factr` which takes default value 1e7.

*GAM convergence and performance issues*

## Description

When fitting GAMs there is a tradeoff between speed of fitting and probability of fit convergence. The default fitting options, specified by [gam](#) arguments `method` and `optimizer`, opt for certainty of convergence over speed of fit. In the Generalized Additive Model case it means using ‘outer’ iteration in preference to ‘performance iteration’: see [gam.outer](#) for details.

It is possible for the default ‘outer’ iteration to fail when finding intial smoothing parameters using a few steps of performance iteration (if you get a convergence failure message from `magic` when outer iterating, then this is what has happened): lower `outerPIsteps` in [gam.control](#) to fix this.

There are three things that you can try to speed up GAM fitting. (i) if you have large numbers of smoothing parameters in the generalized case, then try the “`bfgs`” method option in [gam](#) argument `optimizer`: this can be faster than the default. (ii) Change the `optimizer` argument to [gam](#) so that ‘performance iteration’ is used in place of the default outer iteration. Usually performance iteration converges well and it can sometimes be quicker than the default outer iteration. (iii) For large datasets it may be worth changing the smoothing basis to use `bs="cr"` (see [s](#) for details) for 1-d smooths, and to use `te` smooths in place of [s](#) smooths for smooths of more than one variable. This is because the default thin plate regression spline basis “`tp`” is costly to set up for large datasets (much over 1000 data, say). (iv) consider using [bam](#).

If the GAM estimation process fails to converge when using performance iteration, then switch to outer iteration via the `optimizer` argument of [gam](#). If it still fails, try increasing the number of IRLS iterations (see [gam.control](#)) or perhaps experiment with the convergence tolerance.

If you still have problems, it’s worth noting that a GAM is just a (penalized) GLM and the IRLS scheme used to estimate GLMs is not guaranteed to converge. Hence non convergence of a GAM may relate to a lack of stability in the basic IRLS scheme. Therefore it is worth trying to establish whether the IRLS iterations are capable of converging. To do this fit the problematic GAM with all smooth terms specified with `fx=TRUE` so that the smoothing parameters are all fixed at zero. If this ‘largest’ model can converge then, then the maintainer would quite like to know about your problem! If it doesn’t converge, then its likely that your model is just too flexible for the IRLS process itself. Having tried increasing `maxit` in [gam.control](#), there are several other possibilities for stabilizing the iteration. It is possible to try (i) setting lower bounds on the smoothing parameters using the `min.sp` argument of [gam](#): this may or may not change the model being fitted; (ii) reducing the flexibility of the model by reducing the basis dimensions `k` in the specification of [s](#) and [te](#) model terms: this obviously changes the model being fitted somewhat; (iii) introduce a small regularization term into the fitting via the `irls.reg` argument of [gam.control](#): this option obviously changes the nature of the fit somewhat, since parameter estimates are pulled towards zero by doing this.

Usually, a major contributer to fitting difficulties is that the model is a very poor description of the data.

`gam.fit`

*GAM P-IRLS estimation with GCV/UBRE smoothness estimation*

### Description

This is an internal function of package `mgcv`. It is a modification of the function `glm.fit`, designed to be called from `gam`. The major modification is that rather than solving a weighted least squares problem at each IRLS step, a weighted, penalized least squares problem is solved at each IRLS step with smoothing parameters associated with each penalty chosen by GCV or UBRE, using routine `magic`. For further information on usage see code for `gam`. Some regularization of the IRLS weights is also permitted as a way of addressing identifiability related problems (see `gam.control`). Negative binomial parameter estimation is supported.

The basic idea of estimating smoothing parameters at each step of the P-IRLS is due to Gu (1992), and is termed ‘performance iteration’ or ‘performance oriented iteration’.

### Usage

```
gam.fit(G, start = NULL, etastart = NULL,
 mustart = NULL, family = gaussian(),
 control = gam.control(), gamma=1,
 fixedSteps=(control$maxit+1), ...)
```

### Arguments

|                         |                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>G</code>          | An object of the type returned by <code>gam</code> when <code>fit=FALSE</code> .                                      |
| <code>start</code>      | Initial values for the model coefficients.                                                                            |
| <code>etastart</code>   | Initial values for the linear predictor.                                                                              |
| <code>mustart</code>    | Initial values for the expected response.                                                                             |
| <code>family</code>     | The family object, specifying the distribution and link to use.                                                       |
| <code>control</code>    | Control option list as returned by <code>gam.control</code> .                                                         |
| <code>gamma</code>      | Parameter which can be increased to up the cost of each effective degree of freedom in the GCV or AIC/UBRE objective. |
| <code>fixedSteps</code> | How many steps to take: useful when only using this routine to get rough starting values for other methods.           |
| ...                     | Other arguments: ignored.                                                                                             |

*P-IRLS GAM estimation with GCV\& UBRE/AIC or RE/ML derivative calculation*

**Description**

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC, GCV, GACV, REML or ML score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine estimates a GAM (any quadratically penalized GLM) given log smoothing parameters, and evaluates derivatives of the smoothness selection scores of the model with respect to the log smoothing parameters. Calculation of exact derivatives is generally faster than approximating them by finite differencing, as well as generally improving the reliability of GCV/UBRE/AIC/REML score minimization.

The approach is to run the P-IRLS to convergence, and only then to iterate for first and second derivatives.

Not normally called directly, but rather service routines for [gam](#).

**Usage**

```
gam.fit3(x, y, sp, Eb ,UrS=list(),
 weights = rep(1, nobs), start = NULL, etastart = NULL,
 mustart = NULL, offset = rep(0, nobs), U1 = diag(ncol(x)),
 Mp = -1, family = gaussian(), control = gam.control(),
 intercept = TRUE, deriv=2, gamma=1, scale=1,
 printWarn=TRUE, scoreType="REML", null.coef=rep(0,ncol(x)),
 pearson.extra=0, dev.extra=0, n.true=-1, ...)
```

### Arguments

|               |                                                                                                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x             | The model matrix for the GAM (or any penalized GLM).                                                                                                                                             |
| y             | The response variable.                                                                                                                                                                           |
| sp            | The log smoothing parameters.                                                                                                                                                                    |
| Eb            | A balanced version of the total penalty matrix: used for numerical rank determination.                                                                                                           |
| UrS           | List of square root penalties premultiplied by transpose of orthogonal basis for the total penalty.                                                                                              |
| weights       | prior weights for fitting.                                                                                                                                                                       |
| start         | optional starting parameter guesses.                                                                                                                                                             |
| etastart      | optional starting values for the linear predictor.                                                                                                                                               |
| mustart       | optional starting values for the mean.                                                                                                                                                           |
| offset        | the model offset                                                                                                                                                                                 |
| U1            | An orthogonal basis for the range space of the penalty — required for ML smoothness estimation only.                                                                                             |
| Mp            | The dimension of the total penalty null space — required for ML smoothness estimation only.                                                                                                      |
| family        | the family - actually this routine would never be called with gaussian()                                                                                                                         |
| control       | control list as returned from <a href="#">glm.control</a>                                                                                                                                        |
| intercept     | does the model have an intercept, TRUE or FALSE                                                                                                                                                  |
| deriv         | Should derivatives of the GCV and UBRE/AIC scores be calculated? 0, 1 or 2, indicating the maximum order of differentiation to apply.                                                            |
| gamma         | The weight given to each degree of freedom in the GCV and UBRE scores can be varied (usually increased) using this parameter.                                                                    |
| scale         | The scale parameter - needed for the UBRE/AIC score.                                                                                                                                             |
| printWarn     | Set to FALSE to suppress some warnings. Useful in order to ensure that some warnings are only printed if they apply to the final fitted model, rather than an intermediate used in optimization. |
| scoreType     | specifies smoothing parameter selection criterion to use.                                                                                                                                        |
| null.coef     | coefficients for a model which gives some sort of upper bound on deviance. This allows immediate divergence problems to be controlled.                                                           |
| pearson.extra | Extra component to add to numerator of pearson statistic in P-REML/P-ML smoothness selection criteria.                                                                                           |
| dev.extra     | Extra component to add to deviance for REML/ML type smoothness selection criteria.                                                                                                               |
| n.true        | Number of data to assume in smoothness selection criteria. <=0 indicates that it should be the number of rows of X.                                                                              |
| ...           | Other arguments: ignored.                                                                                                                                                                        |

### Details

This routine is basically [glm.fit](#) with some modifications to allow (i) for quadratic penalties on the log likelihood; (ii) derivatives of the model coefficients with respect to log smoothing parameters to be obtained by use of the implicit function theorem and (iii) derivatives of the GAM GCV, UBRE/AIC, REML or ML scores to be evaluated at convergence.

In addition the routines apply step halving to any step that increases the penalized deviance substantially.

The most costly parts of the calculations are performed by calls to compiled C code (which in turn calls LAPACK routines) in place of the compiled code that would usually perform least squares estimation on the working model in the IRLS iteration.

Estimation of smoothing parameters by optimizing GCV scores obtained at convergence of the P-IRLS iteration was proposed by O'Sullivan et al. (1986), and is here termed 'outer' iteration.

Note that use of non-standard families with this routine requires modification of the families as described in [fix.family.link](#).

### Description

This page is intended to provide some more information on how to specify GAMs. A GAM is a GLM in which the linear predictor depends, in part, on a sum of smooth functions of predictors and (possibly) linear functionals of smooth functions of (possibly dummy) predictors.

Specifically let  $y_i$  denote an independent random variable with mean  $\mu_i$  and an exponential family distribution, or failing that a known mean variance relationship suitable for use of quasi-likelihood methods. Then the the linear predictor of a GAM has a structure something like

$$g(\mu_i) = \mathbf{X}_i\beta + f_1(x_{1i}, x_{2i}) + f_2(x_{3i}) + L_i f_3(x_4) + \dots$$

where  $g$  is a known smooth monotonic 'link' function,  $\mathbf{X}_i\beta$  is the parametric part of the linear predictor, the  $x_j$  are predictor variables, the  $f_j$  are smooth functions and  $L_i$  is some linear functional of  $f_3$ . There may of course be multiple linear functional terms, or none.

The key idea here is that the dependence of the response on the predictors can be represented as a parametric sub-model plus the sum of some (functionals of) smooth functions of one or more of the predictor variables. Thus the model is quite flexible relative to strictly parametric linear or

generalized linear models, but still has much more structure than the completely general model that says that the response is just some smooth function of all the covariates.

Note one important point. In order for the model to be identifiable the smooth functions usually have to be constrained to have zero mean (usually taken over the set of covariate values). The constraint is needed if the term involving the smooth includes a constant function in its span. `gam` always applies such constraints unless there is a `by` variable present, in which case an assessment is made of whether the constraint is needed or not (see below).

The following sections discuss specifying model structures for `gam`. Specification of the distribution and link function is done using the `family` argument to `gam` and works in the same way as for `glm`. This page therefore concentrates on the model formula for `gam`.

### Models with simple smooth terms

Consider the example model.

$$g(\mu_i) = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + f_1(x_{3i}) + f_2(x_{4i}, x_{5i})$$

where the response variables  $y_i$  has expectation  $\mu_i$  and  $g$  is a link function.

The `gam` formula for this would be

$$y \sim x1 + x2 + s(x3) + s(x4, x5).$$

This would use the default basis for the smooths (a thin plate regression spline basis for each), with automatic selection of the effective degrees of freedom for both smooths. The dimension of the smoothing basis is given a default value as well (the dimension of the basis sets an upper limit on the maximum possible degrees of freedom for the basis - the limit is typically one less than basis dimension). Full details of how to control smooths are given in `s` and `te`, and further discussion of basis dimension choice can be found in `choose.k`. For the moment suppose that we would like to change the basis of the first smooth to a cubic regression spline basis with a dimension of 20, while fixing the second term at 25 degrees of freedom. The appropriate formula would be:

$$y \sim x1 + x2 + s(x3, bs="cr", k=20) + s(x4, x5, k=26, fx=TRUE).$$

The above assumes that  $x_4$  and  $x_5$  are naturally on similar scales (e.g. they might be co-ordinates), so that isotropic smoothing is appropriate. If this assumption is false then tensor product smoothing might be better (see `te`).

$$y \sim x1 + x2 + s(x3) + te(x4, x5)$$

would generate a tensor product smooth of  $x_4$  and  $x_5$ . By default this smooth would have basis dimension 25 and use cubic regression spline marginals. Varying the defaults is easy. For example

$$y \sim x1 + x2 + s(x3) + te(x4, x5, bs=c("cr", "ps"), k=c(6, 7))$$

specifies that the tensor product should use a rank 6 cubic regression spline marginal and a rank 7 P-spline marginal to create a smooth with basis dimension 42.

### Nested terms

Another common modelling task is to decide if a model like:

$$E(y_i) = f(x_i, z_i)$$

is really necessary or whether:

$$E(y_i) = f_1(x_i) + f_2(z_i)$$

would do just as well. One possibility is to examine the results of fitting:

$$y \sim s(x) + s(z) + s(x, z).$$

`gam` automatically generates side conditions to make this model identifiable. You can also estimate ‘overlapping’ models like:

$$y \sim s(x, z) + s(z, v).$$

Note that optimum interpretability of such models is obtained by ensuring that lower order terms are strictly nested within higher order ones. This is most easily achieved by employing tensor product smooths for multidimensional terms, and ensuring that lower order terms are using the same (marginal) bases as higher order ones. For example:

`y ~ s(x,bs="cr",k=5) + s(z,bs="cr",k=5) + te(x,z)`

would ensure strict nesting of the main effects within the interaction (given the `te` default `bs` and `k` arguments), since the main effects employ the same bases used as marginals for the `te` term.

### 'by' variables

`by` variables are the means for constructing ‘varying-coefficient models’ (geographic regression models) and for letting smooths ‘interact’ with factors or parametric terms. They are also the key to specifying general linear functionals of smooths.

The `s` and `te` terms used to specify smooths accept an argument `by`, which is a numeric or factor variable of the same dimension as the covariates of the smooth. If a `by` variable is numeric, then its  $i^{th}$  element multiples the  $i^{th}$  row of the model matrix corresponding to the smooth term concerned.

Factor smooth interactions (see also `factor.smooth.interaction`). If a `by` variable is a `factor` then it generates an indicator vector for each level of the factor, unless it is an `ordered` factor. In the non-ordered case, the model matrix for the smooth term is then replicated for each factor level, and each copy has its rows multiplied by the corresponding rows of its indicator variable. The smoothness penalties are also duplicated for each factor level. In short a different smooth is generated for each factor level (the `id` argument to `s` and `te` can be used to force all such smooths to have the same smoothing parameter). `ordered` `by` variables are handled in the same way, except that no smooth is generated for the first level of the ordered factor (see b3 example below). This is useful for setting up identifiable models when the same smooth occurs more than once in a model, with different factor `by` variables.

As an example, consider the model

$$E(y_i) = \beta_0 + f(x_i)z_i$$

where  $f$  is a smooth function, and  $z_i$  is a numeric variable. The appropriate formula is:

`y ~ s(x,by=z)`

- the `by` argument ensures that the smooth function gets multiplied by covariate `z`. Note that when using factor `by` variables, centering constraints are applied to the smooths, which usually means that the `by` variable should be included as a parametric term, as well.

The example code below also illustrates the use of factor `by` variables.

`by` variables may be supplied as numeric matrices as part of specifying general linear functional terms.

If a `by` variable is present and numeric (rather than a factor) then the corresponding smooth is only subjected to an identifiability constraint if (i) the `by` variable is a constant vector, or, (ii) for a matrix `by` variable, `L`, if `L %*% rep(1, ncol(L))` is constant or (iii) if a user defined smooth constructor supplies an identifiability constraint explicitly, and that constraint has an attribute “`always.apply`”.

### Linking smooths with ‘id’

It is sometimes desirable to insist that different smooth terms have the same degree of smoothness. This can be done by using the `id` argument to `s` or `te` terms. Smooths which share an `id` will have the same smoothing parameter. Really this only makes sense if the smooths use the same basis functions, and the default behaviour is to force this to happen: all smooths sharing an `id` have the same basis functions as the first smooth occurring with that `id`. Note that if you want exactly the same function for each smooth, then this is best achieved by making use of the summation convention covered under ‘linear functional terms’.

As an example suppose that  $E(y_i) \equiv \mu_i$  and

$$g(\mu_i) = f_1(x_{1i}) + f_2(x_{2i}, x_{3i}) + f_3(x_{4i})$$

but that  $f_1$  and  $f_3$  should have the same smoothing parameters (and  $x_2$  and  $x_3$  are on different scales). Then the `gam` formula

`y ~ s(x1, id=1) + te(x_2, x3) + s(x4, id=1)`

would achieve the desired result. `id` can be numbers or character strings. Giving an `id` to a term with a factor by variable causes the smooths at each level of the factor to have the same smoothing parameter.

Smooth term `ids` are not supported by `gamm`.

### Linear functional terms

General linear functional terms have a long history in the spline literature including in the penalized GLM context (see e.g. Wahba 1990). Such terms encompass varying coefficient models/ geographic regression, functional GLMs (i.e. GLMs with functional predictors), GLASS models, etc, and allow smoothing with respect to aggregated covariate values, for example.

Such terms are implemented in `mvcv` using a simple ‘summation convention’ for smooth terms: If the covariates of a smooth are supplied as matrices, then summation of the evaluated smooth over the columns of the matrices is implied. Each covariate matrix and any by variable matrix must be of the same dimension. Consider, for example the term

`s(X, Z, by=L)`

where  $X$ ,  $Z$  and  $L$  are  $n \times p$  matrices. Let  $f$  denote the thin plate regression spline specified. The resulting contribution to the  $i^{\text{th}}$  element of the linear predictor is

$$\sum_{j=1}^p L_{ij} f(X_{ij}, Z_{ij})$$

If no  $L$  is supplied then all its elements are taken as 1. In R code terms, let  $F$  denote the  $n \times p$  matrix obtained by evaluating the smooth at the values in  $X$  and  $Z$ . Then the contribution of the term to the linear predictor is `rowSums(L*F)` (note that it’s element by element multiplication here!).

The summation convention applies to `te` terms as well as `s` terms. More details and examples are provided in [linear.functional.terms](#).

### Random effects

Random effects can be added to `gam` models using `s(..., bs="re")` terms (see [smooth.construct.re.smooth.spec](#)), or the `paraPen` argument to `gam` covered below. See `gam.vcomp`, `random.effects` and `smooth.construct.re.smooth.spec` for further details. An alternative is to use the approach of `gamm`.

### Penalizing the parametric terms

In case the ability to add smooth classes, smooth identities, by variables and the summation convention are still not sufficient to implement exactly the penalized GLM that you require, `gam` also allows you to penalize the parametric terms in the model formula. This is mostly useful in allowing one or more matrix terms to be included in the formula, along with a sequence of quadratic penalty matrices for each.

Suppose that you have set up a model matrix  $X$ , and want to penalize the corresponding coefficients,  $\beta$  with two penalties  $\beta^T S_1 \beta$  and  $\beta^T S_2 \beta$ . Then something like the following would be appropriate:

`gam(y ~ X - 1, paraPen=list(X=list(S1, S2)))`

The paraPen argument should be a list with elements having names corresponding to the terms being penalized. Each element of paraPen is itself a list, with optional elements L, rank and sp: all other elements must be penalty matrices. If present, rank is a vector giving the rank of each penalty matrix (if absent this is determined numerically). L is a matrix that maps underlying log smoothing parameters to the log smoothing parameters that actually multiply the individual quadratic penalties: taken as the identity if not supplied. sp is a vector of (underlying) smoothing parameter values: positive values are taken as fixed, negative to signal that the smoothing parameter should be estimated. Taken as all negative if not supplied.

An obvious application of paraPen is to incorporate random effects, and an example of this is provided below. In this case the supplied penalty matrices will be (generalized) inverse covariance matrices for the random effects — i.e. precision matrices. The final estimate of the covariance matrix corresponding to one of these penalties is given by the (generalized) inverse of the penalty matrix multiplied by the estimated scale parameter and divided by the estimated smoothing parameter for the penalty. For example, if you use an identity matrix to penalize some coefficients that are to be viewed as i.i.d. Gaussian random effects, then their estimated variance will be the estimated scale parameter divided by the estimate of the smoothing parameter, for this penalty. See the ‘rail’ example below.

P-values for penalized parametric terms should be treated with caution. If you must have them, then use the option freq=TRUE in `anova.gam` and `summary.gam`, which will tend to give reasonable results for random effects implemented this way, but not for terms with a rank deficient penalty (or penalties with a wide eigen-spectrum).

**gam.outer***Minimize GCV or UBRE score of a GAM using ‘outer’ iteration***Description**

Estimation of GAM smoothing parameters is most stable if optimization of the smoothness selection score (GCV, GACV, UBRE/AIC, REML, ML etc) is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine optimizes a smoothness selection score in this way. Basically the score is evaluated for each trial set of smoothing parameters by estimating the GAM for those smoothing parameters. The score is minimized w.r.t. the parameters numerically, using newton (default), bfgs, optim or nlm. Exact (first and second) derivatives of the score can be used by fitting with [gam.fit3](#). This improves efficiency and reliability relative to relying on finite difference derivatives.

Not normally called directly, but rather a service routine for [gam](#).

**Usage**

```
gam.outer(lsp,fscale,family,control,method,optimizer,
criterion,scale,gamma,G,...)
```

**Arguments**

|                        |                                                                                                                                |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>lsp</code>       | The log smoothing parameters.                                                                                                  |
| <code>fscale</code>    | Typical scale of the GCV or UBRE/AIC score.                                                                                    |
| <code>family</code>    | the model family.                                                                                                              |
| <code>control</code>   | control argument to pass to <a href="#">gam.fit</a> if pure finite differencing is being used.                                 |
| <code>method</code>    | method argument to <a href="#">gam</a> defining the smoothness criterion to use (but depending on whether or not scale known). |
| <code>optimizer</code> | The argument to <a href="#">gam</a> defining the numerical optimization method to use.                                         |
| <code>criterion</code> | Which smoothness selection criterion to use. One of "UBRE", "GCV", "GACV", "REML" or "P-REML".                                 |
| <code>scale</code>     | Supplied scale parameter. Positive indicates known.                                                                            |
| <code>gamma</code>     | The degree of freedom inflation factor for the GCV/UBRE/AIC score.                                                             |
| <code>G</code>         | List produced by <a href="#">mgcv:::gam.setup</a> , containing most of what's needed to actually fit a GAM.                    |
| ...                    | other arguments, typically for passing on to <a href="#">gam.fit3</a> (ultimately).                                            |

*Generalized Additive Model Selection*

---

## Description

This page is intended to provide some more information on how to select GAMs. In particular, it gives a brief overview of smoothness selection, and then discusses how this can be extended to select inclusion/exclusion of terms. Hypothesis testing approaches to the latter problem are also discussed.

## Smoothness selection criteria

Given a model structure specified by a `gam` model formula, `gam()` attempts to find the appropriate smoothness for each applicable model term using prediction error criteria or likelihood based methods. The prediction error criteria used are Generalized (Approximate) Cross Validation (GCV or GACV) when the scale parameter is unknown or an Un-Biased Risk Estimator (UBRE) when it is known. UBRE is essentially scaled AIC (Generalized case) or Mallows’ Cp (additive model case). GCV and UBRE are covered in Craven and Wahba (1979) and Wahba (1990). Alternatively REML of maximum likelihood (ML) may be used for smoothness selection, by viewing the smooth components as random effects (in this case the variance component for each smooth random effect will be given by the scale parameter divided by the smoothing parameter — for smooths with multiple penalties, there will be multiple variance components). The `method` argument to `gam` selects the smoothness selection criterion.

Automatic smoothness selection is unlikely to be successful with few data, particularly with multiple terms to be selected. In addition GCV and UBRE/AIC score can occasionally display local minima that can trap the minimisation algorithms. GCV/UBRE/AIC scores become constant with changing smoothing parameters at very low or very high smoothing parameters, and on occasion these ‘flat’ regions can be separated from regions of lower score by a small ‘lip’. This seems to be the most common form of local minimum, but is usually avoidable by avoiding extreme smoothing parameters as starting values in optimization, and by avoiding big jumps in smoothing parameters while optimizing. Never the less, if you are suspicious of smoothing parameter estimates, try changing fit method (see `gam` arguments `method` and `optimizer`) and see if the estimates change, or try changing some or all of the smoothing parameters ‘manually’ (argument `sp` of `gam`, or `sp` arguments to `s` or `te`).

REML and ML are less prone to local minima than the other criteria, and may therefore be preferable.

### **Automatic term selection**

Unmodified smoothness selection by GCV, AIC, REML etc. will not usually remove a smooth from a model. This is because most smoothing penalties view some space of (non-zero) functions as ‘completely smooth’ and once a term is penalized heavily enough that it is in this space, further penalization does not change it.

However it is straightforward to modify smooths so that under heavy penalization they are penalized to the zero function and thereby ‘selected out’ of the model. There are two approaches.

The first approach is to modify the smoothing penalty with an additional shrinkage term. Smooth classes `cs.smooth` and `tprs.smooth` (specified by “`cs`” and “`ts`” respectively) have smoothness penalties which include a small shrinkage component, so that for large enough smoothing parameters the smooth becomes identically zero. This allows automatic smoothing parameter selection methods to effectively remove the term from the model altogether. The shrinkage component of the penalty is set at a level that usually makes negligible contribution to the penalization of the model, only becoming effective when the term is effectively ‘completely smooth’ according to the conventional penalty.

The second approach leaves the original smoothing penalty unchanged, but constructs an additional penalty for each smooth, which penalizes only functions in the null space of the original penalty (the ‘completely smooth’ functions). Hence, if all the smoothing parameters for a term tend to infinity, the term will be selected out of the model. This latter approach is more expensive computationally, but has the advantage that it can be applied automatically to any smooth term. The `select` argument to `gam` turns on this method.

In fact, as implemented, both approaches operate by eigen-decomposition of the original penalty matrix. A new penalty is created on the null space: it is the matrix with the same eigenvectors as the original penalty, but with the originally positive eigenvalues set to zero, and the originally zero eigenvalues set to something positive. The first approach just adds a multiple of this penalty to the original penalty, where the multiple is chosen so that the new penalty can not dominate the original. The second approach treats the new penalty as an extra penalty, with its own smoothing parameter.

Of course, as with all model selection methods, some care must be taken to ensure that the automatic selection is sensible, and a decision about the effective degrees of freedom at which to declare a term ‘negligible’ has to be made.

### **Interactive term selection**

In general the most logically consistent method to use for deciding which terms to include in the model is to compare GCV/UBRE/ML scores for models with and without the term (REML scores should not be used to compare models with different fixed effects structures). When UBRE is the smoothness selection method this will give the same result as comparing by [AIC](#) (the AIC in this case uses the model EDF in place of the usual model DF). Similarly, comparison via GCV score and via AIC seldom yields different answers. Note that the negative binomial with estimated theta parameter is a special case: the GCV score is not informative, because of the theta estimation scheme used. More generally the score for the model with a smooth term can be compared to the score for the model with the smooth term replaced by appropriate parametric terms. Candidates for replacement by parametric terms are smooth terms with estimated degrees of freedom close to their minimum possible.

Candidates for removal can also be identified by reference to the approximate p-values provided by `summary.gam`, and by looking at the extent to which the confidence band for an estimated term includes the zero function. It is perfectly possible to perform backwards selection using p-values

in the usual way: that is by sequentially dropping the single term with the highest non-significant p-value from the model and re-fitting, until all terms are significant. This suffers from the same problems as stepwise procedures for any GLM/LM, with the additional caveat that the p-values are only approximate. If adopting this approach, it is probably best to use ML smoothness selection.

Note that GCV and UBRE are not appropriate for comparing models using different families: in that case AIC should be used.

### Caveats/platitudes

Formal model selection methods are only appropriate for selecting between reasonable models. If formal model selection is attempted starting from a model that simply doesn't fit the data, then it is unlikely to provide meaningful results.

The more thought is given to appropriate model structure up front, the more successful model selection is likely to be. Simply starting with a hugely flexible model with 'everything in' and hoping that automatic selection will find the right structure is not often successful.

**gam.side***Identifiability side conditions for a GAM*

---

**Description**

GAM formulae with repeated variables only correspond to identifiable models given some side conditions. This routine works out appropriate side conditions, based on zeroing redundant parameters. It is called from `mvcv:::gam.setup` and is not intended to be called by users.

The method identifies nested and repeated variables by their names, but numerically evaluates which constraints need to be imposed. Constraints are always applied to smooths of more variables in preference to smooths of fewer variables. The numerical approach allows appropriate constraints to be applied to models constructed using any smooths, including user defined smooths.

**Usage**

```
gam.side(sm, Xp, tol=.Machine$double.eps^.5, with.pen=FALSE)
```

**Arguments**

|                       |                                                                                                              |
|-----------------------|--------------------------------------------------------------------------------------------------------------|
| <code>sm</code>       | A list of smooth objects as returned by <code>smooth.construct</code> .                                      |
| <code>Xp</code>       | The model matrix for the strictly parametric model components.                                               |
| <code>tol</code>      | The tolerance to use when assessing linear dependence of smooths.                                            |
| <code>with.pen</code> | Should the computation of dependence consider the penalties or not. Doing so will lead to fewer constraints. |

**Details**

Models such as  $y \sim s(x) + s(z) + s(x, z)$  can be estimated by `gam`, but require identifiability constraints to be applied, to make them identifiable. This routine does this, effectively setting redundant parameters to zero. When the redundancy is between smooths of lower and higher numbers of variables, the constraint is always applied to the smooth of the higher number of variables.

Dependent smooths are identified symbolically, but which constraints are needed to ensure identifiability of these smooths is determined numerically, using `fixDependence`. This makes the routine rather general, and not dependent on any particular basis.

`Xp` is used to check whether there is a constant term in the model (or columns that can be linearly combined to give a constant). This is because centred smooths can appear independent, when they would be dependent if there is a constant in the model, so dependence testing needs to take account of this.

**Value**

A list of smooths, with model matrices and penalty matrices adjusted to automatically impose the required constraints. Any smooth that has been modified will have an attribute "del.index", listing the columns of its model matrix that were deleted. This index is used in the creation of prediction matrices for the term.

## Examples

```

set.seed(7)
require(mgcv)
dat <- gamSim(n=400,scale=2) ## simulate data
estimate model with redundant smooth interaction...
b<-gam(y~s(x0)+s(x1)+s(x0,x1)+s(x2),data=dat)
plot(b, pages=1)

Simulate data with real interation...
dat <- gamSim(2,n=500,scale=.1)
old.par<-par(mfrow=c(2,2))
a fully nested tensor product example
b<-gam(y~s(x,bs="cr",k=6)+s(z,bs="cr",k=6)+te(x,z,k=6),
 data=dat$data)
plot(b)

par(old.par)
rm(dat)

```

gam.vcomp

*Report gam smoothness estimates as variance components*

## Description

GAMs can be viewed as mixed models, where the smoothing parameters are related to variance components. This routine extracts the estimated variance components associated with each smooth term, and if possible returns confidence intervals on the standard deviation scale.

## Usage

```
gam.vcomp(x, rescale=TRUE, conf.lev=.95)
```

## Arguments

- |                       |                                                                                                                                                                                                                    |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | a fitted model object of class <code>gam</code> as produced by <code>gam()</code> .                                                                                                                                |
| <code>rescale</code>  | the penalty matrices for smooths are rescaled before fitting, for numerical stability reasons, if <code>TRUE</code> this rescaling is reversed, so that the variance components are on the original scale.         |
| <code>conf.lev</code> | when the smoothing parameters are estimated by REML or ML, then confidence intervals for the variance components can be obtained from large sample likelihood results. This gives the confidence level to work at. |

## Details

The (pseudo) inverse of the penalty matrix penalizing a term is proportional to the covariance matrix of the term's coefficients, when these are viewed as random. For single penalty smooths, it is possible to compute the variance component for the smooth (which multiplies the inverse penalty matrix to obtain the covariance matrix of the smooth's coefficients). This variance component is given by the scale parameter divided by the smoothing parameter.

This routine computes such variance components, for gam models, and associated confidence intervals, if smoothing parameter estimation was likelihood based. Note that variance components are also returned for tensor product smooths, but that their interpretation is not so straightforward.

The routine is particularly useful for model fitted by [gam](#) in which random effects have been incorporated.

### Value

Either a vector of variance components for each smooth term (as standard deviations), or a matrix. The first column of the matrix gives standard deviations for each term, while the subsequent columns give lower and upper confidence bounds, on the same scale.

For models in which there are more smoothing parameters than actually estimated (e.g. if some were fixed, or smoothing parameters are linked) then a list is returned. The `vc` element is as above, the `a11` element is a vector of variance components for all the smoothing parameters (estimated + fixed or replicated).

The routine prints a table of estimated standard deviations and confidence limits, if these can be computed, and reports the numerical rank of the covariance matrix.

### Examples

```
set.seed(3)
require(mgcv)
simulate some data, consisting of a smooth truth + random effects

dat <- gamSim(1,n=400,dist="normal",scale=2)
a <- factor(sample(1:10,400,replace=TRUE))
b <- factor(sample(1:7,400,replace=TRUE))
Xa <- model.matrix(~a-1) ## random main effects
Xb <- model.matrix(~b-1)
Xab <- model.matrix(~a:b-1) ## random interaction
dat$y <- dat$y + Xa%*%rnorm(10)*.5 +
 Xb%*%rnorm(7)*.3 + Xab%*%rnorm(70)*.7
dat$a <- a;dat$b <- b

Fit the model using "re" terms, and smoother linkage

mod <- gam(y~s(a,bs="re") + s(b,bs="re") + s(a,b,bs="re") + s(x0,id=1) + s(x1,id=1) +
 s(x2,k=15) + s(x3), data=dat, method="ML")
```

```
gam.vcomp(mod)
```

**gam2objective***Objective functions for GAM smoothing parameter estimation***Description**

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC or GCV score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters. These functions evaluate the GCV/UBRE/AIC score of a GAM model, given smoothing parameters, in a manner suitable for use by `optim` or `nlm`. Not normally called directly, but rather service routines for `gam.outer`.

**Usage**

```
gam2objective(lsp,args,...)
gam2derivative(lsp,args,...)
```

**Arguments**

- |                   |                                                            |
|-------------------|------------------------------------------------------------|
| <code>lsp</code>  | The log smoothing parameters.                              |
| <code>args</code> | List of arguments required to call <code>gam.fit3</code> . |
| <code>...</code>  | Other arguments for passing to <code>gam.fit3</code> .     |

**Details**

`gam2objective` and `gam2derivative` are functions suitable for calling by `optim`, to evaluate the GCV/UBRE/AIC score and its derivatives w.r.t. log smoothing parameters.

`gam4objective` is an equivalent to `gam2objective`, suitable for optimization by `nlm` - derivatives of the GCV/UBRE/AIC function are calculated and returned as attributes.

The basic idea of optimizing smoothing parameters ‘outer’ to the P-IRLS loop was first proposed in O’Sullivan et al. (1986).

gamm*Generalized Additive Mixed Models*

---

## Description

Fits the specified generalized additive mixed model (GAMM) to data, by a call to `lme` in the normal errors identity link case, or by a call to `gammPQL` (a modification of `glmmPQL` from the MASS library) otherwise. In the latter case estimates are only approximately MLEs. The routine is typically slower than `gam`, and not quite as numerically robust.

To use `lme4` in place of `nlme` as the underlying fitting engine, see `gamm4` from package `gamm4`.

Smooths are specified as in a call to `gam` as part of the fixed effects model formula, but the wiggly components of the smooth are treated as random effects. The random effects structures and correlation structures available for `lme` are used to specify other random effects and correlations.

It is assumed that the random effects and correlation structures are employed primarily to model residual correlation in the data and that the prime interest is in inference about the terms in the fixed effects model formula including the smooths. For this reason the routine calculates a posterior covariance matrix for the coefficients of all the terms in the fixed effects formula, including the smooths.

To use this function effectively it helps to be quite familiar with the use of `gam` and `lme`.

## Usage

```
gamm(formula, random=NULL, correlation=NULL, family=gaussian(),
 data=list(), weights=NULL, subset=NULL, na.action, knots=NULL,
 control=list(niterEM=0, optimMethod="L-BFGS-B"),
 niterPQL=20, verbosePQL=TRUE, method="ML", ...)
```

## Arguments

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>     | A GAM formula (see also <code>formula.gam</code> and <code>gam.models</code> ). This is like the formula for a <code>glm</code> except that smooth terms ( <code>s</code> and <code>te</code> ) can be added to the right hand side of the formula. Note that <code>ids</code> for smooths and fixed smoothing parameters are not supported.                                                                                                                                 |
| <code>random</code>      | The (optional) random effects structure as specified in a call to <code>lme</code> : only the <code>list</code> form is allowed, to facilitate manipulation of the random effects structure within <code>gamm</code> in order to deal with smooth terms. See example below.                                                                                                                                                                                                  |
| <code>correlation</code> | An optional <code>corStruct</code> object (see <code>corClasses</code> ) as used to define correlation structures in <code>lme</code> . Any grouping factors in the formula for this object are assumed to be nested within any random effect grouping factors, without the need to make this explicit in the formula (this is slightly different to the behaviour of <code>lme</code> ). This is a GEE approach to correlation in the generalized case. See examples below. |
| <code>family</code>      | A <code>family</code> as used in a call to <code>glm</code> or <code>gam</code> . The default <code>gaussian</code> with identity link causes <code>gamm</code> to fit by a direct call to <code>lme</code> provided there is no offset term, otherwise <code>gammPQL</code> is used.                                                                                                                                                                                        |
| <code>data</code>        | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>gamm</code> is called.                                                                                                                                                                                                                            |

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| weights    | In the generalized case, weights with the same meaning as <a href="#">glm</a> weights. An <a href="#">lme</a> type weights argument may only be used in the identity link gaussian case, with no offset (see documentation for <a href="#">lme</a> for details of how to use such an argument).                                                                                                                                                                                                                                                                                                                                                       |
| subset     | an optional vector specifying a subset of observations to be used in the fitting process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| na.action  | a function which indicates what should happen when the data contain ‘NA’s. The default is set by the ‘na.action’ setting of ‘options’, and is ‘na.fail’ if that is unset. The “factory-fresh” default is ‘na.omit’.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| knots      | this is an optional list containing user specified knot values to be used for basis construction. Different terms can use different numbers of knots, unless they share a covariate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| control    | A list of fit control parameters for <a href="#">lme</a> to replace the defaults returned by <a href="#">lmeControl</a> . Note the setting for the number of EM iterations used by <a href="#">lme</a> : smooths are set up using custom pdMat classes, which are currently not supported by the EM iteration code. If you supply a list of control values, it is advisable to include niterEM=0, as well, and only increase from 0 if you want to perturb the starting values used in model fitting (usually to worse values!). The optimMethod option is only used if your version of R does not have the <a href="#">nlmnb</a> optimizer function. |
| niterPQL   | Maximum number of PQL iterations (if any).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| verbosePQL | Should PQL report its progress as it goes along?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| method     | Which of "ML" or "REML" to use in the Gaussian additive mixed model case when <a href="#">lme</a> is called directly. Ignored in the generalized case (or if the model has an offset), in which case <a href="#">gammPQL</a> is used.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| ...        | further arguments for passing on e.g. to <a href="#">lme</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

The Bayesian model of spline smoothing introduced by Wahba (1983) and Silverman (1985) opens up the possibility of estimating the degree of smoothness of terms in a generalized additive model as variances of the wiggly components of the smooth terms treated as random effects. Several authors have recognised this (see Wang 1998; Ruppert, Wand and Carroll, 2003) and in the normal errors, identity link case estimation can be performed using general linear mixed effects modelling software such as [lme](#). In the generalized case only approximate inference is so far available, for example using the Penalized Quasi-Likelihood approach of Breslow and Clayton (1993) as implemented in [glmmPQL](#) by Venables and Ripley (2002). One advantage of this approach is that it allows correlated errors to be dealt with via random effects or the correlation structures available in the [nlme](#) library (using correlation structures beyond the strictly additive case amounts to using a GEE approach to fitting).

Some details of how GAMs are represented as mixed models and estimated using [lme](#) or [gammPQL](#) in [gamm](#) can be found in Wood (2004 ,2006a,b). In addition [gamm](#) obtains a posterior covariance matrix for the parameters of all the fixed effects and the smooth terms. The approach is similar to that described in Lin & Zhang (1999) - the covariance matrix of the data (or pseudodata in the generalized case) implied by the weights, correlation and random effects structure is obtained, based on the estimates of the parameters of these terms and this is used to obtain the posterior covariance matrix of the fixed and smooth effects.

The bases used to represent smooth terms are the same as those used in [gam](#), although adaptive smoothing bases are not available.

In the event of [lme](#) convergence failures, consider modifying `option(mgcv.vc.logrange)`: reducing it helps to remove indefiniteness in the likelihood, if that is the problem, but too large a reduction

can force over or undersmoothing. See [notExp2](#) for more information on this option. Failing that, you can try increasing the `niterEM` option in `control`: this will perturb the starting values used in fitting, but usually to values with lower likelihood! Note that this version of `gamm` works best with R 2.2.0 or above and `nlme`, 3.1-62 and above, since these use an improved optimizer.

### Value

Returns a list with two items:

|                  |                                                                                                                                                                                                                                                                                                                                     |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gam</code> | an object of class <code>gam</code> , less information relating to GCV/UBRE model selection. At present this contains enough information to use <code>predict</code> , <code>summary</code> and <code>print</code> methods and <code>vis.gam</code> , but not to use e.g. the <code>anova</code> method function to compare models. |
| <code>lme</code> | the fitted model object returned by <code>lme</code> or <code>gammPQL</code> . Note that the model formulae and grouping structures may appear to be rather bizarre, because of the manner in which the GAMM is split up and the calls to <code>lme</code> and <code>gammPQL</code> are constructed.                                |

### WARNINGS

`gamm` performs poorly with binary data, since it uses PQL. It is better to use `gam` with `s(...,bs="re")` terms, or `gamm4`.

`gamm` assumes that you know what you are doing! For example, unlike `glmmPQL` from MASS it will return the complete `lme` object from the working model at convergence of the PQL iteration, including the ‘log likelihood’, even though this is not the likelihood of the fitted GAMM.

The routine will be very slow and memory intensive if correlation structures are used for the very large groups of data. e.g. attempting to run the spatial example in the examples section with many 1000’s of data is definitely not recommended: often the correlations should only apply within clusters that can be defined by a grouping factor, and provided these clusters do not get too huge then fitting is usually possible.

Models must contain at least one random effect: either a smooth with non-zero smoothing parameter, or a random effect specified in argument `random`.

`gamm` is not as numerically stable as `gam`: an `lme` call will occasionally fail. See details section for suggestions, or try the ‘`gamm4`’ package.

`gamm` is usually much slower than `gam`, and on some platforms you may need to increase the memory available to R in order to use it with large data sets (see [mem.limits](#)).

Note that the weights returned in the fitted GAM object are dummy, and not those used by the PQL iteration: this makes partial residual plots look odd.

Note that the `gam` object part of the returned object is not complete in the sense of having all the elements defined in [gamObject](#) and does not inherit from `glm`: hence e.g. multi-model anova calls will not work.

The parameterization used for the smoothing parameters in `gamm`, bounds them above and below by an effective infinity and effective zero. See [notExp2](#) for details of how to change this.

Linked smoothing parameters and adaptive smoothing are not supported.

b2 <- gam(y~s(x,z,k=50), data=data); plot(b2)
par(old.par)

```

**gamObject***Fitted gam object***Description**

A fitted GAM object returned by function `gam` and of class "gam" inheriting from classes "glm" and "lm". Method functions `anova`, `logLik`, `influence`, `plot`, `predict`, `print`, `residuals` and `summary` exist for this class.

All compulsory elements of "glm" and "lm" objects are present, but the fitting method for a GAM is different to a linear model or GLM, so that the elements relating to the QR decomposition of the model matrix are absent.

**Value**

A `gam` object has the following elements:

|                       |                                                                                                                                                                                                                                                       |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>aic</code>      | AIC of the fitted model: bear in mind that the degrees of freedom used to calculate this are the effective degrees of freedom of the model, and the likelihood is evaluated at the maximum of the penalized likelihood in most cases, not at the MLE. |
| <code>assign</code>   | Array whose elements indicate which model term (listed in <code>pterms</code> ) each parameter relates to: applies only to non-smooth terms.                                                                                                          |
| <code>boundary</code> | did parameters end up at boundary of parameter space?                                                                                                                                                                                                 |

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <code>formula</code>           | the model formula.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>full.sp</code>           | full array of smoothing parameters multiplying penalties (excluding any contribution from <code>min.sp</code> argument to <code>gam</code> ). May be larger than <code>sp</code> if some terms share smoothing parameters, and/or some smoothing parameter values were supplied in the <code>sp</code> argument of <code>gam</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>F</code>                 | Degrees of freedom matrix. This may be removed at some point, and should probably not be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>gcv.ubre</code>          | The minimized smoothing parameter selection score: GCV, UBRE(AIC), GACV, negative log marginal likelihood or negative log restricted likelihood.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>hat</code>               | array of elements from the leading diagonal of the ‘hat’ (or ‘influence’) matrix. Same length as response data vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>iter</code>              | number of iterations of P-IRLS taken to get convergence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>linear.predictors</code> | fitted model prediction of link function of expected value for each datum.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>method</code>            | One of "GCV" or "UBRE", "REML", "P-REML", "ML", "P-ML", "PQL", "lme.ML" or "lme.REML", depending on the fitting criterion used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>mgcv.conv</code>         | A list of convergence diagnostics relating to the "magic" parts of smoothing parameter estimation - this will not be very meaningful for pure "outer" estimation of smoothing parameters. The items are: <code>full.rank</code> , The apparent rank of the problem given the model matrix and constraints; <code>rank</code> , The numerical rank of the problem; <code>fully.converged</code> , TRUE if multiple GCV/UBRE converged by meeting convergence criteria and FALSE if method stopped with a steepest descent step failure; <code>hess.pos.def</code> Was the hessian of the GCV/UBRE score positive definite at smoothing parameter estimation convergence?; <code>iter</code> How many iterations were required to find the smoothing parameters? <code>score.calls</code> , and how many times did the GCV/UBRE score have to be evaluated?; <code>rms.grad</code> , root mean square of the gradient of the GCV/UBRE score at convergence. |
| <code>min.edf</code>           | Minimum possible degrees of freedom for whole model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| model           | model frame containing all variables needed in original model fit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| na.action       | The <code>na.action</code> used in fitting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| nsdf            | number of parametric, non-smooth, model terms including the intercept.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| null.deviance   | deviance for single parameter model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| offset          | model offset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| optimizer       | optimizer argument to <code>gam</code> , or "magic" if it's a pure additive model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| outer.info      | If 'outer' iteration has been used to fit the model (see <code>gam</code> argument <code>optimizer</code> ) then this is present and contains whatever was returned by the optimization routine used (currently <code>nlm</code> or <code>optim</code> ).                                                                                                                                                                                                                                                                                                                  |
| paraPen         | If the paraPen argument to <code>gam</code> was used then this provides information on the parametric penalties. NULL otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| prior.weights   | prior weights on observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| pterms          | terms object for strictly parametric part of model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| R               | Factor R from QR decomposition of weighted model matrix, unpivoted to be in same column order as model matrix (so need not be upper triangular).                                                                                                                                                                                                                                                                                                                                                                                                                           |
| rank            | apparent rank of fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| reml.scale      | The scale (RE)ML scale parameter estimate, if (P-)(RE)ML used for smoothness estimation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| residuals       | the working residuals for the fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| rV              | If present, $rV \otimes t(rV) \otimes \text{sig2}$ gives the estimated Bayesian covariance matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| scale           | when present, the scale (as <code>sig2</code> )                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| scale.estimated | TRUE if the scale parameter was estimated, FALSE otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| sig2            | estimated or supplied variance/scale parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| smooth          | list of smooth objects, containing the basis information for each term in the model formula in the order in which they appear. These smooth objects are what gets returned by the <code>smooth.construct</code> objects.                                                                                                                                                                                                                                                                                                                                                   |
| sp              | estimated smoothing parameters for the model. These are the underlying smoothing parameters, subject to optimization. For the full set of smoothing parameters multiplying the penalties see <code>full.sp</code> . Divide the scale parameter by the smoothing parameters to get, variance components, but note that this is not valid for smooths that have used rescaling to improve conditioning.                                                                                                                                                                      |
| terms           | terms object of <code>model</code> model frame.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| var.summary     | A named list of summary information on the predictor variables. If a parametric variable is a matrix, then the summary is a one row matrix, containing the observed data value closest to the column median, for each matrix column. If the variable is a factor the then summary is the modal factor level, returned as a factor, with levels corresponding to those of the data. For numerics and matrix arguments of smooths, the summary is the mean, nearest observed value to median and maximum, as a numeric vector. Used by <code>vis.gam</code> , in particular. |
| Ve              | frequentist estimated covariance matrix for the parameter estimators. Particularly useful for testing whether terms are zero. Not so useful for CI's as smooths are usually biased.                                                                                                                                                                                                                                                                                                                                                                                        |
| Vp              | estimated covariance matrix for the parameters. This is a Bayesian posterior covariance matrix that results from adopting a particular Bayesian model of the smoothing process. Particularly useful for creating credible/confidence intervals.                                                                                                                                                                                                                                                                                                                            |
| weights         | final weights used in IRLS iteration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| y               | response data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## WARNINGS

This model object is different to that described in Chambers and Hastie (1993) in order to allow smoothing parameter estimation etc.

## Author(s)

*Simulate example data for GAMs*

## Description

Function used to simulate data sets to illustrate the use of [gam](#) and [gamm](#). Mostly used in help files to keep down the length of the example code sections.

## Usage

```
gamSim(eg=1, n=400, dist="normal", scale=2)
```

## Arguments

|       |                                                                                 |
|-------|---------------------------------------------------------------------------------|
| eg    | numeric value specifying the example required.                                  |
| n     | number of data to simulate.                                                     |
| dist  | character string which may be used to specify the distribution of the response. |
| scale | Used to set noise level.                                                        |

## Details

See the source code for exactly what is simulated in each case.

1. Gu and Wahba 4 univariate term example.
2. A smooth function of 2 variables.
3. Example with continuous by variable.
4. Example with factor by variable.
5. An additive example plus a factor variable.
6. Additive + random effect.
7. As 1 but with correlated covariates.

**Value**

Depends on eg, but usually a dataframe, which may also contain some information on the underlying truth. Sometimes a list with more items, including a data frame for model fitting. See source code or helpfile examples where the function is used for further information.

get.var

*Get named variable or evaluate expression from list or data.frame*

---

**Description**

This routine takes a text string and a data frame or list. It first sees if the string is the name of a variable in the data frame/ list. If it is then the value of this variable is returned. Otherwise the routine tries to evaluate the expression within the data.frame/list (but nowhere else) and if successful returns the result. If neither step works then NULL is returned. The routine is useful for processing gam formulae. If the variable is a matrix then it is coerced to a numeric vector, by default.

**Usage**

```
get.var(txt,data,vecMat=TRUE)
```

**Arguments**

|        |                                                                                                                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| txt    | a text string which is either the name of a variable in data or when parsed is an expression that can be evaluated in data. It can also be neither in which case the function returns NULL. |
| data   | A data frame or list.                                                                                                                                                                       |
| vecMat | Should matrices be coerced to numeric vectors?                                                                                                                                              |

**Value**

The evaluated variable or NULL. May be coerced to a numeric vector if it's a matrix.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

<http://www.maths.bath.ac.uk/~sw283/>

**See Also**[gam](#)**Examples**

```
require(mgcv)
y <- 1:4;dat<-data.frame(x=5:10)
get.var("x",dat)
get.var("y",dat)
get.var("x==6",dat)
dat <- list(X=matrix(1:6,3,2))
get.var("X",dat)
```

in.out

*Which of a set of points lie within a polygon defined region***Description**

Tests whether each of a set of points lie within a region defined by one or more (possibly nested) polygons. Points count as ‘inside’ if they are interior to an odd number of polygons.

**Usage**

```
in.out(bnd,x)
```

**Arguments**

- |     |                                                                                                                                                                                                     |
|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bnd | A two column matrix, the rows of which define the vertices of polygons defining the boundary of a region. Different polygons should be separated by an NA row, and the polygons are assumed closed. |
| x   | A two column matrix. Each row is a point to test for inclusion in the region defined by bnd.                                                                                                        |

**Details**

The algorithm works by counting boundary crossings (using compiled C code).

**Value**

A logical vector of length nrow(x). TRUE if the corresponding row of x is inside the boundary and FALSE otherwise.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

**References**

<http://www.maths.bath.ac.uk/~sw283/>

## Examples

```
library(mgcv)
data(columb.polys)
bnd <- columb.polys[[2]]
plot(bnd,type="n")
polygon(bnd)
x <- seq(7.9,8.7,length=20)
y <- seq(13.7,14.3,length=20)
gr <- as.matrix(expand.grid(x,y))
inside <- in.out(bnd,gr)
points(gr,col=as.numeric(inside)+1)
```

---

**influence.gam**

*Extract the diagonal of the influence/hat matrix for a GAM*

---

## Description

Extracts the leading diagonal of the influence matrix (hat matrix) of a fitted `gam` object.

## Usage

```
S3 method for class 'gam'
influence(model,...)
```

## Arguments

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <code>model</code> | fitted model objects of class <code>gam</code> as produced by <code>gam()</code> . |
| <code>...</code>   | un-used in this case                                                               |

## Details

Simply extracts hat array from fitted model. (More may follow!)

## Value

An array (see above).

**initial.sp***Starting values for multiple smoothing parameter estimation*

## Description

Finds initial smoothing parameter guesses for multiple smoothing parameter estimation. The idea is to find values such that the estimated degrees of freedom per penalized parameter should be well away from 0 and 1 for each penalized parameter, thus ensuring that the values are in a region of parameter space where the smoothing parameter estimation criterion is varying substantially with smoothing parameter value.

## Usage

```
initial.sp(X,S,off,expensive=FALSE)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X         | is the model matrix.                                                                                                                                                                                                                                                                                                                                  |
| S         | is a list of of penalty matrices. S[[i]] is the ith penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of S[[i]] occupies element off[i], off[i] of the ith penalty matrix. Each S[[i]] must be positive semi-definite. |
| off       | is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving S[[i]].                                                                                                                                                                                                                                 |
| expensive | if TRUE then the overall amount of smoothing is adjusted so that the average degrees of freedom per penalized parameter is exactly 0.5: this is numerically costly.                                                                                                                                                                                   |

## Details

Basically uses a crude approximation to the estimated degrees of freedom per model coefficient, to try and find smoothing parameters which bound these e.d.f.'s away from 0 and 1.

Usually only called by [magic](#) and [gam](#).

## Value

An array of initial smoothing parameter estimates.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

|        |                                    |
|--------|------------------------------------|
| inSide | <i>Are points inside boundary?</i> |
|--------|------------------------------------|

---

## Description

Assesses whether points are inside a boundary. The boundary must enclose the domain, but may include islands.

## Usage

```
inSide(bnd,x,y)
```

## Arguments

|     |                                                                                                                                                                                                                                                                                |
|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bnd | This should have two equal length columns with names matching whatever is supplied in x and y. This may contain several sections of boundary separated by NA. Alternatively bnd may be a list, each element of which contains 2 columns named as above. See below for details. |
| x   | x co-ordinates of points to be tested.                                                                                                                                                                                                                                         |
| y   | y co-ordinates of points to be tested.                                                                                                                                                                                                                                         |

## Details

Segments of boundary are separated by NAs, or are in separate list elements. The boundary co-ordinates are taken to define nodes which are joined by straight line segments in order to create the boundary. Each segment is assumed to define a closed loop, and the last point in a segment will be assumed to be joined to the first. Loops must not intersect (no test is made for this).

The method used is to count how many times a line, in the y-direction from a point, crosses a boundary segment. An odd number of crossings defines an interior point. Hence in geographic applications it would be usual to have an outer boundary loop, possibly with some inner ‘islands’ completely enclosed in the outer loop.

The routine calls compiled C code and operates by an exhaustive search for each point in x, y.

## Value

The function returns a logical array of the same dimension as x and y. TRUE indicates that the corresponding x, y point lies inside the boundary.

## Examples

```
require(mgcv)
m <- 300;n <- 150
xm <- seq(-1,4,length=m);yn<-seq(-1,1,length=n)
x <- rep(xm,n);y<-rep(yn,rep(m,n))
er <- matrix(fs.test(x,y),m,n)
bnd <- fs.boundary()
in.bnd <- inSide(bnd,x,y)
plot(x,y,col=as.numeric(in.bnd)+1,pch=".")
lines(bndx,bndy,col=3)
points(x,y,col=as.numeric(in.bnd)+1,pch=".")
check boundary details ...
plot(x,y,col=as.numeric(in.bnd)+1,pch=".",ylim=c(-1,0),xlim=c(3,3.5))
lines(bndx,bndy,col=3)
points(x,y,col=as.numeric(in.bnd)+1,pch=".")
```

**interpret.gam**

*Interpret a GAM formula*

## Description

This is an internal function of package `mgcv`. It is a service routine for `gam` which splits off the strictly parametric part of the model formula, returning it as a formula, and interprets the smooth parts of the model formula.

Not normally called directly.

## Usage

```
interpret.gam(gf)
```

## Arguments

|                 |                                                                      |
|-----------------|----------------------------------------------------------------------|
| <code>gf</code> | A GAM formula as supplied to <code>gam</code> or <code>gamm</code> . |
|-----------------|----------------------------------------------------------------------|

## Value

An object of class `split.gam.formula` with the following items:

|                           |                                                                                                                                                                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pf</code>           | A model formula for the strictly parametric part of the model.                                                                                                                                                                           |
| <code>pfok</code>         | TRUE if there is a <code>pf</code> formula.                                                                                                                                                                                              |
| <code>smooth.spec</code>  | A list of class <code>xx.smooth.spec</code> objects where <code>xx</code> depends on the basis specified for the term. (These can be passed to <code>smooth</code> constructor method functions to actually set up penalties and bases.) |
| <code>full.formula</code> | An expanded version of the model formula in which the options are fully expanded, and the options do not depend on variables which might not be available later.                                                                         |
| <code>fake.formula</code> | A formula suitable for use in evaluating a model frame.                                                                                                                                                                                  |
| <code>response</code>     | Name of the response variable.                                                                                                                                                                                                           |

ldTweedie

*Log Tweedie density evaluation*

---

**Description**

A function to evaluate the log of the Tweedie density for variance powers between 1 and 2, inclusive. Also evaluates first and second derivatives of log density w.r.t. its scale parameter.

**Usage**

```
ldTweedie(y, mu=y, p=1.5, phi=1)
```

**Arguments**

|     |                                                                                                                                                    |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------|
| y   | values at which to evaluate density.                                                                                                               |
| mu  | corresponding means (either of same length as y or a single value).                                                                                |
| p   | the variance of y is proportional to its mean to the power p. p must be between 1 and 2. 1 is Poisson like (exactly Poisson if phi=1), 2 is gamma. |
| phi | The scale parameter. Variance of y is phi*mu^p.                                                                                                    |

**Details**

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution. The  $p=1$  case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For  $1 < p < 2$  the distribution is supported on the positive reals with a point mass at zero.  $p=2$  is a gamma distribution. As  $p$  gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at  $p=1$ .

ldTweedie is based on the series evaluation method of Dunn and Smyth (2005). Without the restriction on  $p$  the calculation of Tweedie densities is less straightforward. If you really need this case then the tweedie package is the place to start.

**Value**

A matrix with 3 columns. The first is the log density of y (log probability if  $p=1$ ). The second and third are the first and second derivatives of the log density w.r.t. phi.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org> modified from Venables and Ripley's negative.binomial family.

**Examples**

```
library(mgcv)
convergence to Poisson illustrated
notice how p>1.1 is OK
y <- seq(1e-10,10,length=1000)
p <- c(1.0001,1.001,1.01,1.1,1.2,1.5,1.8,2)
phi <- .5
fy <- exp(ldTweedie(y,mu=2,p=p[1],phi=phi)[,1])
plot(y,fy,type="l",ylim=c(0,3),main="Tweedie density as p changes")
for (i in 2:length(p)) {
 fy <- exp(ldTweedie(y,mu=2,p=p[i],phi=phi)[,1])
 lines(y,fy,col=i)
}
```

**Description**

`gam` allows the response variable to depend on linear functionals of smooth terms. Specifically dependancies of the form

$$g(\mu_i) = \dots + \sum_j L_{ij} f(x_{ij}) + \dots$$

are allowed, where the  $x_{ij}$  are covariate values and the  $L_{ij}$  are fixed weights. i.e. the response can depend on the weighted sum of the same smooth evaluated at different covariate values. This allows, for example, for the response to depend on the derivatives or integrals of a smooth (approximated by finite differencing or quadrature, respectively). It also allows dependence on predictor functions (sometimes called 'signal regression').

The mechanism by which this is achieved is to supply matrices of covariate values to the model smooth terms specified by `s` or `te` terms in the model formula. Each column of the covariate matrix gives rise to a corresponding column of predictions from the smooth. Let the resulting matrix of evaluated smooth values be `F` (`F` will have the same dimension as the covariate matrices). In the absense of a `by` variable then these columns are simply summed and added to the linear predictor. i.e. the contribution of the term to the linear predictor is `rowSums(F)`. If a `by` variable is present

then it must be a matrix, L,say, of the same dimension as F (and the covariate matrices), and it contains the weights  $L_{ij}$  in the summation given above. So in this case the contribution to the linear predictor is `rowSums(L*F)`.

Note that if a `L1` (i.e. `rowSums(L)`) is a constant vector, or there is no by variable then the smooth will automatically be centred in order to ensure identifiability. Otherwise it will not be. Note also that for centred smooths it can be worth replacing the constant term in the model with `rowSums(L)` in order to ensure that predictions are automatically on the right scale.

When predicting from the model it is not necessary to provide matrix covariate and by variable values. For example to simply examine the underlying smooth function one would use vectors of covariate values and vector by variables, with the by variable and equivalent of `L1`, above, set to vectors of ones.

### Examples

```
matrix argument 'linear operator' smoothing
library(mgcv)
set.seed(0)

#####
simple summation example...
#####

n<-400
sig<-2
x <- runif(n, 0, .9)
f2 <- function(x) 0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10
x1 <- x + .1

f <- f2(x) + f2(x1) ## response is sum of f at two adjacent x values
y <- f + rnorm(n)*sig

X <- matrix(c(x,x1),n,2) ## matrix covariate contains both x values
b <- gam(y~s(X))

plot(b) ## reconstruction of f
plot(f,fitted(b))

#####
multivariate integral example. Function 'test1' will be integrated#
(by midpoint quadrature) over 100 equal area sub-squares covering
the unit square. Noise is added to the resulting simulated data.
'test1' is estimated from the resulting data using two alternative#
smooths.
#####

test1 <- function(x,z,sx=0.3,sz=0.4)
{ (pi**sx*sz)*(1.2*exp(-(x-0.2)^2/sx^2-(z-0.3)^2/sz^2) +
 0.8*exp(-(x-0.7)^2/sx^2-(z-0.8)^2/sz^2))
}

create quadrature (integration) grid, in useful order
```

```

ig <- 5 ## integration grid within square
mx <- mz <- (1:ig-.5)/ig
ix <- rep(mx,ig);iz <- rep(mz,rep(ig,ig))

og <- 10 ## observarion grid
mx <- mz <- (1:og-1)/og
ox <- rep(mx,og);ox <- rep(ox,rep(ig^2,og^2))
oz <- rep(mz,rep(og,og));oz <- rep(oz,rep(ig^2,og^2))

x <- ox + ix/og;z <- oz + iz/og ## full grid, subsquare by subsquare

create matrix covariates...
X <- matrix(x,og^2,ig^2,byrow=TRUE)
Z <- matrix(z,og^2,ig^2,byrow=TRUE)

create simulated test data...
dA <- 1/(og*ig)^2 ## quadrature square area
F <- test1(X,Z) ## evaluate on grid
f <- rowSums(F)*dA ## integrate by midpoint quadrature
y <- f + rnorm(og^2)*5e-4 ## add noise
... so each y is a noisy observation of the integral of 'test1'
over a 0.1 by 0.1 sub-square from the unit square

Now fit model to simulated data...

L <- X*0 + dA

... let F be the matrix of the smooth evaluated at the x,z values
in matrices X and Z. rowSums(L*F) gives the model predicted
integrals of 'test1' corresponding to the observed 'y'

L1 <- rowSums(L) ## smooths are centred --- need to add in L%*%1

fit models to reconstruct 'test1'.....

b <- gam(y~s(X,Z,by=L)+L1-1) ## (L1 and const are confounded here)
b1 <- gam(y~te(X,Z,by=L)+L1-1) ## tensor product alternative

plot results...

old.par<-par(mfrow=c(2,2))
x<-runif(n);z<-runif(n);
xs<-seq(0,1,length=30);zs<-seq(0,1,length=30)
pr<-data.frame(x=rep(xs,30),z=rep(zs,rep(30,30)))
truth<-matrix(test1(prx,prz),30,30)
contour(xs,zs,truth)
plot(b)
vis.gam(b,view=c("X","Z"),cond=list(L1=1,L=1),plot.type="contour")
vis.gam(b1,view=c("X","Z"),cond=list(L1=1,L=1),plot.type="contour")

#####
A "signal" regression example...#
#####

rf <- function(x=seq(0,1,length=100)) {
generates random functions...
 m <- ceiling(runif(1)*5) ## number of components

```

```

f <- x*0;
mu <- runif(m,min(x),max(x));sig <- (runif(m)+.5)*(max(x)-min(x))/10
for (i in 1:m) f <- f+ dnorm(x,mu[i],sig[i])
f
}

x <- seq(0,1,length=100) ## evaluation points

example functional predictors...
par(mfrow=c(3,3));for (i in 1:9) plot(x,rf(x),type="l",xlab="x")

simulate 200 functions and store in rows of L...
L <- matrix(NA,200,100)
for (i in 1:200) L[i,] <- rf() ## simulate the functional predictors

f2 <- function(x) { ## the coefficient function
 (0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10)/10
}
f <- f2(x) ## the true coefficient function

y <- L%*%f + rnorm(200)*20 ## simulated response data

Now fit the model E(y) = L%*%f(x) where f is a smooth function.
The summation convention is used to evaluate smooth at each value
in matrix X to get matrix F, say. Then rowSum(L*F) gives E(y).

create matrix of eval points for each function. Note that
'smoothCon' is smart and will recognize the duplication...
X <- matrix(x,200,100,byrow=TRUE)

b <- gam(y~s(X,by=L,k=20))
par(mfrow=c(1,1))
plot(b,shade=TRUE);lines(x,f,col=2)

```

**logLik.gam***Extract the log likelihood for a fitted GAM***Description**

Function to extract the log-likelihood for a fitted `gam` model (note that the models are usually fitted by penalized likelihood maximization).

**Usage**

```
S3 method for class 'gam'
logLik(object,...)
```

**Arguments**

- |                     |                                                                                    |
|---------------------|------------------------------------------------------------------------------------|
| <code>object</code> | fitted model objects of class <code>gam</code> as produced by <code>gam()</code> . |
| <code>...</code>    | un-used in this case                                                               |

## Details

Modification of `logLik.glm` which corrects the degrees of freedom for use with `gam` objects.

The function is provided so that [AIC](#) functions correctly with `gam` objects, and uses the appropriate degrees of freedom (accounting for penalization). Note, when using AIC for penalized models, that the degrees of freedom are the effective degrees of freedom and not the number of parameters, and the model maximizes the penalized likelihood, not the actual likelihood! This seems to be reasonably well founded for the known scale parameter case (see Hastie and Tibshirani, 1990, section 6.8.3 and also Wood 2008), and in fact in this case the default smoothing parameter estimation criterion is effectively this modified AIC.

## Value

Standard `logLik` object: see [logLik](#).

`ls.size`

*Size of list elements*

## Description

Produces a named array giving the size, in bytes, of the elements of a list.

## Usage

`ls.size(x)`

## Arguments

`x` A list.

## Value

A numeric vector giving the size in bytes of each element of the list `x`. The elements of the array have the same names as the elements of the list. If `x` is not a list then its size in bytes is returned, un-named.

## Examples

```
library(mgcv)
b <- list(M=matrix(runif(100),10,10),quote=
"The world is ruled by idiots because only an idiot would want to rule the world.",
fam=binomial())
ls.size(b)
```

magic

*Stable Multiple Smoothing Parameter Estimation by GCV or UBRE*

## Description

Function to efficiently estimate smoothing parameters in generalized ridge regression problems with multiple (quadratic) penalties, by GCV or UBRE. The function uses Newton's method in multi-dimensions, backed up by steepest descent to iteratively adjust the smoothing parameters for each penalty (one penalty may have a smoothing parameter fixed at 1).

For maximal numerical stability the method is based on orthogonal decomposition methods, and attempts to deal with numerical rank deficiency gracefully using a truncated singular value decomposition approach.

## Usage

```
magic(y,X,S,off,L=NULL,lsp0=NULL,rank=NULL,H=NULL,C=NULL,
 w=NULL,gamma=1,scale=1,gcv=TRUE,ridge.parameter=NULL,
 control=list(tol=1e-6,step.half=25,
 rank.tol=.Machine$double.eps^0.5),extra.rss=0,n.score=length(y))
```

## Arguments

- |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y   | is the response data vector.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| X   | is the model matrix (more columns than rows are allowed).                                                                                                                                                                                                                                                                                                                                                                                                                     |
| sp  | is the array of smoothing parameters. The vector $L\%*\%log(sp) + lsp0$ contains the logs of the smoothing parameters that actually multiply the penalty matrices stored in S (L is taken as the identity if NULL). Any sp values that are negative are autoinitialized, otherwise they are taken as supplying starting values. A supplied starting value will be reset to a default starting value if the gradient of the GCV/UBRE score is too small at the supplied value. |
| S   | is a list of of penalty matrices. S[[i]] is the ith penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of S[[i]] occupies element off[i], off[i] of the ith penalty matrix. Each S[[i]] must be positive semi-definite. Set to list() if there are no smoothing parameters to be estimated.                                                     |
| off | is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving S[[i]].                                                                                                                                                                                                                                                                                                                                                         |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| L               | is a matrix mapping $\log(sp)$ to the log smoothing parameters that actually multiply the penalties defined by the elements of S. Taken as the identity, if NULL. See above under sp.                                                                                                                                                                                                                                                                                             |
| lsp0            | If L is not NULL this is a vector of constants in the linear transformation from $\log(sp)$ to the actual log smoothing parameters. So the logs of the smoothing parameters multiplying the $S[[i]]$ are given by $L * \log(sp) + lsp0$ . Taken as 0 if NULL.                                                                                                                                                                                                                     |
| rank            | is an array specifying the ranks of the penalties. This is useful, but not essential, for forming square roots of the penalty matrices.                                                                                                                                                                                                                                                                                                                                           |
| H               | is the optional offset penalty - i.e. a penalty with a smoothing parameter fixed at 1. This is useful for allowing regularization of the estimation process, fixed smoothing penalties etc.                                                                                                                                                                                                                                                                                       |
| C               | is the optional matrix specifying any linear equality constraints on the fitting problem. If b is the parameter vector then the parameters are forced to satisfy $Cb = 0$ .                                                                                                                                                                                                                                                                                                       |
| w               | the regression weights. If this is a matrix then it is taken as being the square root of the inverse of the covariance matrix of y, specifically $V_y^{-1} = w'w$ . If w is an array then it is taken as the diagonal of this matrix, or simply the weight for each element of y. See below for an example using this.                                                                                                                                                            |
| gamma           | is an inflation factor for the model degrees of freedom in the GCV or UBRE score.                                                                                                                                                                                                                                                                                                                                                                                                 |
| scale           | is the scale parameter for use with UBRE.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| gcv             | should be set to TRUE if GCV is to be used, FALSE for UBRE.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ridge.parameter | It is sometimes useful to apply a ridge penalty to the fitting problem, penalizing the parameters in the constrained space directly. Setting this parameter to a value greater than zero will cause such a penalty to be used, with the magnitude given by the parameter value.                                                                                                                                                                                                   |
| control         | is a list of iteration control constants with the following elements:<br><b>tol</b> The tolerance to use in judging convergence.<br><b>step.half</b> If a trial step fails then the method tries halving it up to a maximum of <b>step.half</b> times.<br><b>rank.tol</b> is a constant used to test for numerical rank deficiency of the problem. Basically any singular value less than <b>rank_tol</b> multiplied by the largest singular value of the problem is set to zero. |
| extra.rss       | is a constant to be added to the residual sum of squares (squared norm) term in the calculation of the GCV, UBRE and scale parameter estimate. In conjunction with n.score, this is useful for certain methods for dealing with very large data sets.                                                                                                                                                                                                                             |
| n.score         | number to use as the number of data in GCV/UBRE score calculation: usually the actual number of data, but there are methods for dealing with very large datasets that change this.                                                                                                                                                                                                                                                                                                |

## Details

The method is a computationally efficient means of applying GCV or UBRE (often approximately AIC) to the problem of smoothing parameter selection in generalized ridge regression problems of the form:

$$\text{minimise } \|\mathbf{W}(\mathbf{X}\mathbf{b} - \mathbf{y})\|^2 + \mathbf{b}'\mathbf{H}\mathbf{b} + \sum_{i=1}^m \theta_i \mathbf{b}'\mathbf{S}_i \mathbf{b}$$

possibly subject to constraints  $\mathbf{C}\mathbf{b} = \mathbf{0}$ .  $\mathbf{X}$  is a design matrix,  $\mathbf{b}$  a parameter vector,  $\mathbf{y}$  a data vector,  $\mathbf{W}$  a weight matrix,  $\mathbf{S}_i$  a positive semi-definite matrix of coefficients defining the  $i$ th penalty with associated smoothing parameter  $\theta_i$ ,  $\mathbf{H}$  is the positive semi-definite offset penalty matrix and  $\mathbf{C}$  a matrix of coefficients defining any linear equality constraints on the problem.  $\mathbf{X}$  need not be of full column rank.

The  $\theta_i$  are chosen to minimize either the GCV score:

$$V_g = \frac{n\|\mathbf{W}(\mathbf{y} - \mathbf{A}\mathbf{y})\|^2}{[tr(\mathbf{I} - \gamma\mathbf{A})]^2}$$

or the UBRE score:

$$V_u = \|\mathbf{W}(\mathbf{y} - \mathbf{A}\mathbf{y})\|^2/n - 2\phi tr(\mathbf{I} - \gamma\mathbf{A})/n + \phi$$

where  $\gamma$  is gamma the inflation factor for degrees of freedom (usually set to 1) and  $\phi$  is scale, the scale parameter.  $\mathbf{A}$  is the hat matrix (influence matrix) for the fitting problem (i.e the matrix mapping data to fitted values). Dependence of the scores on the smoothing parameters is through  $\mathbf{A}$ .

The method operates by Newton or steepest descent updates of the logs of the  $\theta_i$ . A key aspect of the method is stable and economical calculation of the first and second derivatives of the scores w.r.t. the log smoothing parameters. Because the GCV/UBRE scores are flat w.r.t. very large or very small  $\theta_i$ , it's important to get good starting parameters, and to be careful not to step into a flat region of the smoothing parameter space. For this reason the algorithm rescales any Newton step that would result in a  $\log(\theta_i)$  change of more than 5. Newton steps are only used if the Hessian of the GCV/UBRE is positive definite, otherwise steepest descent is used. Similarly steepest descent is used if the Newton step has to be contracted too far (indicating that the quadratic model underlying Newton is poor). All initial steepest descent steps are scaled so that their largest component is 1. However a step is calculated, it is never expanded if it is successful (to avoid flat portions of the objective), but steps are successively halved if they do not decrease the GCV/UBRE score, until they do, or the direction is deemed to have failed. (Given the smoothing parameters the optimal b parameters are easily found.)

The method is coded in C with matrix factorizations performed using LINPACK and LAPACK routines.

## Value

The function returns a list with the following items:

|                 |                                                                                                                                                                                                           |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>b</b>        | The best fit parameters given the estimated smoothing parameters.                                                                                                                                         |
| <b>scale</b>    | the estimated (GCV) or supplied (UBRE) scale parameter.                                                                                                                                                   |
| <b>score</b>    | the minimized GCV or UBRE score.                                                                                                                                                                          |
| <b>sp</b>       | an array of the estimated smoothing parameters.                                                                                                                                                           |
| <b>sp.full</b>  | an array of the smoothing parameters that actually multiply the elements of S (same as sp if L was NULL). This is $\exp(L\%*\%log(sp))$ .                                                                 |
| <b>rV</b>       | a factored form of the parameter covariance matrix. The (Bayesian) covariance matrix of the parameters b is given by $rV\%*\%t(rV)*scale$ .                                                               |
| <b>gcv.info</b> | is a list of information about the performance of the method with the following elements:<br><b>full.rank</b> The apparent rank of the problem: number of parameters less number of equality constraints. |

**rank** The estimated actual rank of the problem (at the final iteration of the method).

**fully.converged** is TRUE if the method converged by satisfying the convergence criteria, and FALSE if it converged by failing to decrease the score along the search direction.

**hess.pos.def** is TRUE if the hessian of the UBRE or GCV score was positive definite at convergence.

**iter** is the number of Newton/Steepest descent iterations taken.

**score.calls** is the number of times that the GCV/UBRE score had to be evaluated.

**rms.grad** is the root mean square of the gradient of the UBRE/GCV score w.r.t. the smoothing parameters.

**R** The factor R from the QR decomposition of the weighted model matrix. This is un-pivoted so that column order corresponds to X. So it may not be upper triangular.

Note that some further useful quantities can be obtained using [magic.post.proc](#).

## Examples

```
Use 'magic' for a standard additive model fit ...
library(mgcv)
set.seed(1);n <- 200;sig <- 1
dat <- gamSim(1,n=n,scale=sig)
k <- 30
set up additive model
G <- gam(y~s(x0,k=k)+s(x1,k=k)+s(x2,k=k)+s(x3,k=k),fit=FALSE,data=dat)
fit using magic (and gam default tolerance)
mgfit <- magic(Gy,GX,Gsp,GS,G$off,rank=G$rank,
 control=list(tol=1e-7,step.half=15))
and fit using gam as consistency check
b <- gam(G=G)
mgfit$sp;b$sp # compare smoothing parameter estimates
edf <- magic.post.proc(G$X,mgfit,G$w)$edf # get e.d.f. per param
range(edf-b$edf) # compare

p>n example... fit model to first 100 data only, so more
params than data...
mgfit <- magic(G$y[1:100],G$X[1:100,],Gsp,GS,G$off,rank=G$rank)
```

```

edf <- magic.post.proc(G$X[1:100,],mgfit,G$w[1:100])$edf

constrain first two smooths to have identical smoothing parameters
L <- diag(3);L <- rbind(L[1,],L)
mgfit <- magic(Gy,GX,rep(-1,3),GS,Goff,L=L,rank=G$rank,C=G$C)

Now a correlated data example ...
library(nlme)
simulate truth
set.seed(1);n<-400;sig<-2
x <- 0:(n-1)/(n-1)
f <- 0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10
produce scaled covariance matrix for AR1 errors...
V <- corMatrix(Initialize(corAR1(.6),data.frame(x=x)))
Cv <- chol(V) # t(Cv)%*%Cv=V
Simulate AR1 errors ...
e <- t(Cv)%*%rnorm(n,0,sig) # so cov(e) = V * sig^2
Observe truth + AR1 errors
y <- f + e
GAM ignoring correlation
par(mfrow=c(1,2))
b <- gam(y~s(x,k=20))
plot(b);lines(x,f-mean(f),col=2);title("Ignoring correlation")
Fit smooth, taking account of *known* correlation...
w <- solve(t(Cv)) # V^{-1} = w'w
Use 'gam' to set up model for fitting...
G <- gam(y~s(x,k=20),fit=FALSE)
fit using magic, with weight *matrix*
mgfit <- magic(Gy,GX,Gsp,GS,G$off,rank=G$rank,C=G$C,w=w)
Modify previous gam object using new fit, for plotting...
mg.stuff <- magic.post.proc(G$X,mgfit,w)
b$edf <- mg.stuff$edf;b$Vp <- mg.stuff$Vb
b$coefficients <- mgfit$b
plot(b);lines(x,f-mean(f),col=2);title("Known correlation")

```

**magic.post.proc***Auxilliary information from magic fit***Description**

Obtains Bayesian parameter covariance matrix, frequentist parameter estimator covariance matrix, estimated degrees of freedom for each parameter and leading diagonal of influence/hat matrix, for a penalized regression estimated by **magic**.

**Usage**

```
magic.post.proc(X,object,w)
```

**Arguments**

- |        |                                                                                   |
|--------|-----------------------------------------------------------------------------------|
| X      | is the model matrix.                                                              |
| object | is the list returned by <b>magic</b> after fitting the model with model matrix X. |

`w`

is the weight vector used in fitting, or the weight matrix used in fitting (i.e. supplied to `magic`, if one was.). If `w` is a vector then its elements are typically proportional to reciprocal variances (but could even be negative). If `w` is a matrix then `t(w)%*%w` should typically give the inverse of the covariance matrix of the response data supplied to `magic`.

## Details

object contains `rV` ( $\mathbf{V}$ , say), and `scale` ( $\phi$ , say) which can be used to obtain the require quantities as follows. The Bayesian covariance matrix of the parameters is  $\mathbf{V}\mathbf{V}'\phi$ . The vector of estimated degrees of freedom for each parameter is the leading diagonal of  $\mathbf{V}\mathbf{V}'\mathbf{X}'\mathbf{W}'\mathbf{W}\mathbf{X}\mathbf{V}\mathbf{V}'$  where  $\mathbf{W}$  is either the weight matrix `w` or the matrix `diag(w)`. The hat/influence matrix is given by  $\mathbf{W}\mathbf{X}\mathbf{V}\mathbf{V}'\mathbf{X}'\mathbf{W}'$ .

The frequentist parameter estimator covariance matrix is  $\mathbf{V}\mathbf{V}'\mathbf{X}'\mathbf{W}'\mathbf{W}\mathbf{X}\mathbf{V}\mathbf{V}'\phi$ : it is sometimes useful for testing terms for equality to zero.

## Value

A list with three items:

|                  |                                                                                   |
|------------------|-----------------------------------------------------------------------------------|
| <code>Vb</code>  | the Bayesian covariance matrix of the model parameters.                           |
| <code>Ve</code>  | the frequentist covariance matrix for the parameter estimators.                   |
| <code>hat</code> | the leading diagonal of the hat (influence) matrix.                               |
| <code>edf</code> | the array giving the estimated degrees of freedom associated with each parameter. |

## Description

This page provides answers to some of the questions that get asked most often about mgcv

## FAQ list

1. **How can I compare gamm models?** In the identity link normal errors case, then AIC and hypothesis testing based methods are fine. Otherwise it is best to work out a strategy based on the [summary.gam](#) Alternatively, simple random effects can be fitted with [gam](#), which makes comparison straightforward. Package [gamm4](#) is an alternative, which allows AIC type model selection for generalized models.

2. **How do I get the equation of an estimated smooth?** This slightly misses the point of semi-parametric modelling: the idea is that we estimate the form of the function from data without assuming that it has a particular simple functional form. Of course for practical computation the functions do have underlying mathematical representations, but they are not very helpful, when written down. If you do need the functional forms then see chapter 4 of Wood (2006). However for most purposes it is better to use `predict.gam` to evaluate the function for whatever argument values you need. If derivatives are required then the simplest approach is to use finite differencing (which also allows SEs etc to be calculated).
3. **Some of my smooths are estimated to be straight lines and their confidence intervals vanish at some point in the middle. What is wrong?** Nothing. Smooths are subject to sum-to-zero identifiability constraints. If a smooth is estimated to be a straight line then it consequently has one degree of freedom, and there is no choice about where it passes through zero — so the CI must vanish at that point.
4. **Some code from Wood (2006) causes an error: why?** The book was written using mgcv version 1.3. To allow for REML estimation of smoothing parameters in versions 1.5, some changes had to be made to the syntax. In particular the function `gam.method` no longer exists. The smoothness selection method (GCV, REML etc) is now controlled by the `method` argument to `gam` while the optimizer is selected using the `optimizer` argument. See `gam` and <http://www.maths.bath.ac.uk/~sw283/igam/index.html> for details.
5. **Why is a model object saved under a previous mgcv version not usable with the current mgcv version?** I'm sorry about this issue, I know it's really annoying. Here's my defence. Each mgcv version is run through an extensive test suite before release, to ensure that it gives the same results as before, unless there are good statistical reasons why not (e.g. improvements to p-value approximation, fixing of an error). However it is sometimes necessary to modify the internal structure of model objects in a way that makes an old style object unusable with a newer version. For example, bug fixes or new R features sometimes require changes in the way that things are computed which in turn require modification of the object structure. Similarly improvements, such as the ability to compute smoothing parameters by RE/ML require object level changes. The only fix to this problem is to access the old object using the original mgcv version (available on CRAN), or to recompute the fit using the current mgcv version.
6. **When using gamm or gamm4, the reported AIC is different for the gam object and the lme or lmer object. Why is this?** There are several reasons for this. The most important is that the models being used are actually different in the two representations. When treating the GAM as a mixed model, you are implicitly assuming that if you gathered a replicate dataset, the smooths in your model would look completely different to the smooths from the original model, except for having the same degree of smoothness. Technically you would expect the smooths to be drawn afresh from their distribution under the random effects model. When viewing the `gam` from the usual penalized regression perspective, you would expect smooths to look broadly similar under replication of the data. i.e. you are really using Bayesian model for the smooths, rather than a random effects model (it's just that the frequentist random effects and Bayesian computations happen to coincide for computing the estimates). As a result of the different assumptions about the data generating process, AIC model comparisons can give rather different answers depending on the model adopted. Which you use should depend on which model you really think is appropriate. In addition the computations of the AICs are different. The mixed model AIC uses the marginal likelihood and the corresponding number of model parameters. The `gam` model uses the penalized likelihood and the effective degrees of freedom.
7. **What does 'mgcv' stand for?** 'Mixed GAM Computation Vehicle', is my current best effort (let me know if you can do better). Originally it stood for 'Multiple GCV', which has long since ceased to be usefully descriptive, (and I can't really change 'mgcv' now without causing disruption).

8. **My new method is failing to beat mgcv, what can I do?** If speed is the problem, then make sure that you use the slowest basis possible ("tp") with a large sample size, and experiment with different optimizers to find one that is slow for your problem. For prediction error/MSE, then leaving the smoothing basis dimensions at their arbitrary defaults, when these are inappropriate for the problem setting, is a good way of reducing performance. Similarly, using p-splines in place of derivative penalty based splines will often shave a little more from the performance here. Unlike REML/ML, prediction error based smoothness selection criteria such as Mallows Cp and GCV often produce a small proportion of severe overfits, so careful choice of smoothness selection method can help further. In particular GCV etc. usually result in worse confidence interval and p-value performance than ML or REML. If all this fails, try using a really odd simulation setup for which mgcv is clearly not suited: for example poor performance is almost guaranteed for small noisy datasets with large numbers of predictors.

**model.matrix.gam**

*Extract model matrix from GAM fit*

### Description

Obtains the model matrix from a fitted gam object.

### Usage

```
S3 method for class 'gam'
model.matrix(object, ...)
```

### Arguments

|        |                                                                                   |
|--------|-----------------------------------------------------------------------------------|
| object | fitted model object of class <code>gam</code> as produced by <code>gam()</code> . |
| ...    | other arguments, passed to <code><a href="#">predict.gam</a></code> .             |

### Details

Calls `predict.gam` with no newdata argument and type="lpmatrix" in order to obtain the model matrix of `object`.

### Value

A model matrix.

## See Also

[gam](#)

## Examples

```
require(mgcv)
n <- 15
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=6),knots=list(x=seq(0,1,length=6)))
model.matrix(mod)
```

mono.con

*Monotonicity constraints for a cubic regression spline*

## Description

Finds linear constraints sufficient for monotonicity (and optionally upper and/or lower boundedness) of a cubic regression spline. The basis representation assumed is that given by the `gam`, "cr" basis: that is the spline has a set of knots, which have fixed x values, but the y values of which constitute the parameters of the spline.

## Usage

```
mono.con(x, up=TRUE, lower=NA, upper=NA)
```

## Arguments

- |                    |                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------|
| <code>x</code>     | The array of knot locations.                                                                          |
| <code>up</code>    | If TRUE then the constraints imply increase, if FALSE then decrease.                                  |
| <code>lower</code> | This specifies the lower bound on the spline unless it is NA in which case no lower bound is imposed. |
| <code>upper</code> | This specifies the upper bound on the spline unless it is NA in which case no upper bound is imposed. |

## Details

Consider the natural cubic spline passing through the points  $\{x_i, p_i : i = 1 \dots n\}$ . Then it is possible to find a relatively small set of linear constraints on  $\mathbf{p}$  sufficient to ensure monotonicity (and bounds if required):  $\mathbf{Ap} \geq \mathbf{b}$ . Details are given in Wood (1994).

## Value

a list containing constraint matrix  $\mathbf{A}$  and constraint vector  $\mathbf{b}$ .

**mroot**

*Smallest square root of matrix*

**Description**

Find a square root of a positive semi-definite matrix, having as few columns as possible. Uses either pivoted choleski decomposition or singular value decomposition to do this.

**Usage**

```
mroot(A, rank=NULL, method="chol")
```

**Arguments**

- |        |                                                                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A      | The positive semi-definite matrix, a square root of which is to be found.                                                                                                                           |
| rank   | if the rank of the matrix A is known then it should be supplied.                                                                                                                                    |
| method | "chol" to use pivoted choleski decompositon, which is fast but tends to overestimate rank. "svd" to use singular value decomposition, which is slow, but is the most accurate way to estimate rank. |

**Details**

The routine uses an LAPACK SVD routine, or the LINPACK pivoted Choleski routine. It is primarily of use for turning penalized regression problems into ordinary regression problems.

**Value**

A matrix, **B** with as many columns as the rank of **A**, and such that **A = BB'**.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

## Examples

```
require(mgcv)
set.seed(0)
a <- matrix(runif(24),6,4)
A <- a%*%t(a) ## A is +ve semi-definite, rank 4
B <- mroot(A) ## default pivoted choleski method
tol <- 100*.Machine$double.eps
chol.err <- max(abs(A-B%*%t(B)));chol.err
if (chol.err>tol) warning("mroot (chol) suspect")
B <- mroot(A,method="svd") ## svd method
svd.err <- max(abs(A-B%*%t(B)));svd.err
if (svd.err>tol) warning("mroot (svd) suspect")
```

negbin

*GAM negative binomial family*

## Description

The `gam` modelling function is designed to be able to use the `negbin` family (a modification of MASS library `negative.binomial` family by Venables and Ripley), with or without a known  $\theta$  parameter. Two approaches to estimating the theta parameter are available:

- If ‘performance iteration’ is used for smoothing parameter estimation (see `gam`), then smoothing parameters are chosen by GCV and theta is chosen in order to ensure that the Pearson estimate of the scale parameter is as close as possible to 1, the value that the scale parameter should have.
- If ‘outer iteration’ is used for smoothing parameter selection, and smoothing parameters are chosen by UBRE/AIC (with scale parameter set to 1) then a value of theta is searched for which minimizes the AIC of the model. Alternatively If (RE)ML is used for smoothing parameter estimation then a value of theta is searched for which maximizes the (restricted) likelihood.

The second option is much slower than the first, but the first can sometimes fail to converge. To use the first option, set the `optimizer` argument of `gam` to “perf”.

## Usage

```
negbin(theta = stop("'theta' must be specified"), link = "log")
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>theta</code> | Either i) a single value known value of theta, ii) two values of theta specifying the endpoints of an interval over which to search for theta or iii) an array of values of theta, specifying the set of theta values to search. (iii) is only available with AIC based theta estimation. |
| <code>link</code>  | The link function: one of “log”, “identity” or “sqrt”                                                                                                                                                                                                                                     |

## Details

If a single value of theta is supplied then it is always taken as the known fixed value, and estimation of smoothing parameters is then by UBRE/AIC. If theta is two numbers (theta[2]>theta[1]) then they are taken as specifying the range of values over which to search for the optimal theta. If theta is any other array of numbers then they are taken as the discrete set of values of theta over which to search for theta. The latter option only works with AIC based outer iteration, if performance iteration is used then an array will only be used to define a search range.

If performance iteration is used (see `gam` argument `optimizer`) then the method of estimation is to choose  $\hat{\theta}$  so that the GCV (Pearson) estimate of the scale parameter is one (since the scale parameter is one for the negative binomial). In this case  $\theta$  estimation is nested within the IRLS loop used for GAM fitting. After each call to fit an iteratively weighted additive model to the IRLS pseudodata, the  $\theta$  estimate is updated. This is done by conditioning on all components of the current GCV/Pearson estimator of the scale parameter except  $\theta$  and then searching for the  $\hat{\theta}$  which equates this conditional estimator to one. The search is a simple bisection search after an initial crude line search to bracket one. The search will terminate at the upper boundary of the search region is a Poisson fit would have yielded an estimated scale parameter <1.

If outer iteration is used then  $\theta$  is estimated by searching for the value yielding the lowest AIC. The search is either over the supplied array of values, or is a grid search over the supplied range, followed by a golden section search. A full fit is required for each trial  $\theta$ , so the process is slow, but speed is enhanced by making the changes in  $\theta$  as small as possible, from one step to the next, and using the previous smoothing parameter and fitted values to start the new fit.

In a simulation test based on 800 replicates of the first example data, given below, the GCV based (performance iteration) method yielded models with, on average 6% better MSE performance than the AIC based (outer iteration) method. theta had a 0.86 correlation coefficient between the two methods. theta estimates averaged 3.36 with a standard deviation of 0.44 for the AIC based method and 3.22 with a standard deviation of 0.43 for the GCV based method. However the GCV based method is less computationally reliable, failing in around 4% of replicates.

## Value

An object inheriting from class `family`, with additional elements

|                       |                                                                                                                                     |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>dvar</code>     | the function giving the first derivative of the variance function w.r.t. <code>mu</code> .                                          |
| <code>d2var</code>    | the function giving the second derivative of the variance function w.r.t. <code>mu</code> .                                         |
| <code>getTheta</code> | A function for retrieving the value(s) of theta. This also useful for retrieving the estimate of theta after fitting (see example). |

## WARNINGS

`gamm` does not support theta estimation

The negative binomial functions from the MASS library are no longer supported.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)> modified from Venables and Ripley's `negative.binomial` family.

## Examples

```

library(mgcv)
set.seed(3)
n<-400
dat <- gamSim(1,n=n)
g <- exp(dat$f/5)

negative binomial data
dat$y <- rnbinom(g,size=3,mu=g)
known theta ...
b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negbin(3),data=dat)
plot(b,pages=1)
print(b)

unknown theta via performance iteration...
b1 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negbin(c(1,10)),
 optimizer="perf",data=dat)
plot(b1,pages=1)
print(b1)

unknown theta via outer iteration and AIC search
(quite slow, which is why it's commented out for
checking)...
Not run:
b2<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negbin(c(1,10)),
 data=dat)
plot(b2,pages=1)
print(b2)

Same again all by REML...
b2a <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negbin(c(1,10)),
 data=dat,method="REML")
plot(b2a,pages=1)
print(b2a)

how to retrieve Theta...
b2a$family$getTheta()

End(Not run)

unknown theta via outer iteration and AIC search
over a discrete set of values...
b3<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negbin(2:10/2),
 data=dat)
plot(b3,pages=1)
print(b3)

another example...
set.seed(1)
f <- dat$f
f <- f - min(f);g <- f^2
dat$y <- rnbinom(g,size=3,mu=g)
b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negbin(1:10,link="sqrt"),
 data=dat)
plot(b,pages=1)
print(b)

```

```
rm(dat)
```

---

**new.name**

*Obtain a name for a new variable that is not already in use*

---

## Description

`gamm` works by transforming a GAMM into something that can be estimated by `lme`, but this involves creating new variables, the names of which should not clash with the names of other variables on which the model depends. This simple service routine checks a suggested name against a list of those in use, and if necessary modifies it so that there is no clash.

## Usage

```
new.name(proposed,old.names)
```

## Arguments

|                        |                                               |
|------------------------|-----------------------------------------------|
| <code>proposed</code>  | a suggested name                              |
| <code>old.names</code> | An array of names that must not be duplicated |

## Value

A name that is not in `old.names`.

## Author(s)

Simon N. Wood <simon.wood@r-project.org>

## References

<http://www.maths.bath.ac.uk/~sw283/>

## Examples

```
require(mgcv)
old <- c("a","tuba","is","tubby")
new.name("tubby",old)
```

## Description

It is common practice in statistical optimization to use log-parameterizations when a parameter ought to be positive. i.e. if an optimization parameter  $a$  should be non-negative then we use  $a=\exp(b)$  and optimize with respect to the unconstrained parameter  $b$ . This often works well, but it does imply a rather limited working range for  $b$ : using 8 byte doubles, for example, if  $b$ 's magnitude gets much above 700 then  $a$  overflows or underflows. This can cause problems for numerical optimization methods.

notExp is a monotonic function for mapping the real line into the positive real line with much less extreme underflow and overflow behaviour than exp. It is a piece-wise function, but is continuous to second derivative: see the source code for the exact definition, and the example below to see what it looks like.

notLog is the inverse function of notExp.

The major use of these functions was originally to provide more robust pdMat classes for lme for use by gamm. Currently the notExp2 and notLog2 functions are used in their place, as a result of changes to the nlme optimization routines.

## Usage

```
notExp(x)
```

```
notLog(x)
```

## Arguments

x Argument array of real numbers (notExp) or positive real numbers (notLog).

## Value

An array of function values evaluated at the supplied argument values.

## Author(s)

Simon N. Wood <simon.wood@r-project.org>

## References

<http://www.maths.bath.ac.uk/~sw283/>

## Examples

```
Illustrate the notExp function:
less steep than exp, but still monotonic.
require(mgcv)
x <- -100:100/10
op <- par(mfrow=c(2,2))
plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
x <- x/4
plot(x,notExp(x),type="l")
lines(x,exp(x),col=2)
plot(x,log(notExp(x)),type="l")
lines(x,log(exp(x)),col=2) # redundancy intended
par(op)
range(notLog(notExp(x))-x) # show that inverse works!
```

## notExp2

*Alternative to log parameterization for variance components*

## Description

notLog2 and notExp2 are alternatives to log and exp or [notLog](#) and [notExp](#) for re-parameterization of variance parameters. They are used by the [pdTens](#) and [pdIdnot](#) classes which in turn implement smooths for [gamm](#).

The functions are typically used to ensure that smoothing parameters are positive, but the notExp2 is not monotonic: rather it cycles between ‘effective zero’ and ‘effective infinity’ as its argument changes. The notLog2 is the inverse function of the notExp2 only over an interval centered on zero.

Parameterizations using these functions ensure that estimated smoothing parameters remain positive, but also help to ensure that the likelihood is never indefinite: once a working parameter pushes a smoothing parameter below ‘effective zero’ or above ‘effective infinity’ the cyclic nature of the notExp2 causes the likelihood to decrease, where otherwise it might simply have flattened.

This parameterization is really just a numerical trick, in order to get `lme` to fit `gamm` models, without failing due to indefiniteness. Note in particular that asymptotic results on the likelihood/REML criterion are not invalidated by the trick, unless parameter estimates end up close to the effective zero or effective infinity: but if this is the case then the asymptotics would also have been invalid for a conventional monotonic parameterization.

This reparameterization was made necessary by some modifications to the underlying optimization method in `lme` introduced in nlme 3.1-62. It is possible that future releases will return to the [notExp](#) parameterization.

Note that you can reset ‘effective zero’ and ‘effective infinity’: see below.

## Usage

```
notExp2(x,d=.Options$mgcv.vc.logrange,b=1/d)
```

```
notLog2(x,d=.Options$mgcv.vc.logrange,b=1/d)
```

**Arguments**

- x Argument array of real numbers (notExp) or positive real numbers (notLog).
- d the range of notExp2 runs from  $\exp(-d)$  to  $\exp(d)$ . To change the range used by gamm reset mgcv.vc.logrange using [options](#).
- b determines the period of the cycle of notExp2.

**Value**

An array of function values evaluated at the supplied argument values.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

<http://www.maths.bath.ac.uk/~sw283/>

```

null.space.dimension    *The basis of the space of un-penalized functions for a TPRS*

**Description**

The thin plate spline penalties give zero penalty to some functions. The space of these functions is spanned by a set of polynomial terms. `null.space.dimension` finds the dimension of this space,  $M$ , given the number of covariates that the smoother is a function of,  $d$ , and the order of the smoothing penalty,  $m$ . If  $m$  does not satisfy  $2m > d$  then the smallest possible dimension for the null space is found given  $d$  and the requirement that the smooth should be visually smooth.

**Usage**

`null.space.dimension(d,m)`

**Arguments**

- d** is a positive integer - the number of variables of which the t.p.s. is a function.
- m** a non-negative integer giving the order of the penalty functional, or signalling that the default order should be used.

**Details**

Thin plate splines are only visually smooth if the order of the wigginess penalty,  $m$ , satisfies  $2m > d + 1$ . If  $2m < d + 1$  then this routine finds the smallest  $m$  giving visual smoothness for the given  $d$ , otherwise the supplied  $m$  is used. The null space dimension is given by:

$$M = (m + d - 1)!/(d!(m - 1)!)$$

which is the value returned.

**Value**

An integer (array), the null space dimension  $M$ .

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

<http://www.maths.bath.ac.uk/~sw283/>

**See Also**

[tprs](#)

**Examples**

```
require(mgcv)
null.space.dimension(2,0)
```

**Description**

Solves least squares problems with quadratic penalties subject to linear equality and inequality constraints using quadratic programming.

**Usage**

`pcls(M)`

## Arguments

- M** is the single list argument to pccls. It should have the following elements:
- y** The response data vector.
  - w** A vector of weights for the data (often proportional to the reciprocal of the variance).
  - X** The design matrix for the problem, note that ncol(M\$X) must give the number of model parameters, while nrow(M\$X) should give the number of data.
  - C** Matrix containing any linear equality constraints on the problem (e.g. **C** in  $\mathbf{C}\mathbf{p} = \mathbf{c}$ ). If you have no equality constraints initialize this to a zero by zero matrix. Note that there is no need to supply the vector **c**, it is defined implicitly by the initial parameter estimates **p**.
  - S** A list of penalty matrices.  $S[[i]]$  is the smallest contiguous matrix including all the non-zero elements of the ith penalty matrix. The first parameter it penalizes is given by off[i]+1 (starting counting at 1).
  - off** Offset values locating the elements of M\$S in the correct location within each penalty coefficient matrix. (Zero offset implies starting in first location)
  - sp** An array of smoothing parameter estimates.
  - p** An array of feasible initial parameter estimates - these must satisfy the constraints, but should avoid satisfying the inequality constraints as equality constraints.
  - Ain** Matrix for the inequality constraints  $\mathbf{A}_{in}\mathbf{p} > \mathbf{b}_{in}$ .
  - bin** vector in the inequality constraints.

## Details

This solves the problem:

$$\text{minimise } \|\mathbf{W}^{1/2}(\mathbf{X}\mathbf{p} - \mathbf{y})\|^2 + \sum_{i=1}^m \lambda_i \mathbf{p}' \mathbf{S}_i \mathbf{p}$$

subject to constraints  $\mathbf{C}\mathbf{p} = \mathbf{c}$  and  $\mathbf{A}_{in}\mathbf{p} > \mathbf{b}_{in}$ , w.r.t.  $\mathbf{p}$  given the smoothing parameters  $\lambda_i$ .  $\mathbf{X}$  is a design matrix,  $\mathbf{p}$  a parameter vector,  $\mathbf{y}$  a data vector,  $\mathbf{W}$  a diagonal weight matrix,  $\mathbf{S}_i$  a positive semi-definite matrix of coefficients defining the ith penalty and  $\mathbf{C}$  a matrix of coefficients defining the linear equality constraints on the problem. The smoothing parameters are the  $\lambda_i$ . Note that  $\mathbf{X}$  must be of full column rank, at least when projected into the null space of any equality constraints.  $\mathbf{A}_{in}$  is a matrix of coefficients defining the inequality constraints, while  $\mathbf{b}_{in}$  is a vector involved in defining the inequality constraints.

Quadratic programming is used to perform the solution. The method used is designed for maximum stability with least squares problems: i.e.  $\mathbf{X}'\mathbf{X}$  is not formed explicitly. See Gill et al. 1981.

## Value

The function returns an array containing the estimated parameter vector.

**pdIdnot***Overflow proof pdMat class for multiples of the identity matrix***Description**

This set of functions is a modification of the `pdMat` class `pdIdent` from library `nlme`. The modification is to replace the log parameterization used in `pdMat` with a `notLog2` parameterization, since the latter avoids indefiniteness in the likelihood and associated convergence problems: the parameters also relate to variances rather than standard deviations, for consistency with the `pdTens` class. The functions are particularly useful for working with Generalized Additive Mixed Models where variance parameters/smoothing parameters can be very large or very small, so that overflow or underflow can be a problem.

These functions would not normally be called directly, although unlike the `pdTens` class it is easy to do so.

**Usage**

```
pdIdnot(value = numeric(0), form = NULL,
 nam = NULL, data = sys.frame(sys.parent()))
```

**Arguments**

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <code>value</code> | Initialization values for parameters. Not normally used.     |
| <code>form</code>  | A one sided formula specifying the random effects structure. |
| <code>nam</code>   | a names argument, not normally used with this class.         |
| <code>data</code>  | data frame in which to evaluate formula.                     |

**Details**

The following functions are provided: `Dim.pdIdnot`, `coef.pdIdnot`, `corMatrix.pdIdnot`, `logDet.pdIdnot`, `pdConstruct.pdIdnot`, `pdFactor.pdIdnot`, `pdMatrix.pdIdnot`, `solve.pdIdnot`, `summary.pdIdnot`. (e.g. `mgcv:::coef.pdIdnot` to access.)

Note that while the `pdFactor` and `pdMatrix` functions return the inverse of the scaled random effect covariance matrix or its factor, the `pdConstruct` function is initialised with estimates of the scaled covariance matrix itself.

**Value**

A class `pdIdnot` object, or related quantities. See the `nlme` documentation for further details.

**pdTens**

*Functions implementing a pdMat class for tensor product smooths*

**Description**

This set of functions implements an nlme library pdMat class to allow tensor product smooths to be estimated by lme as called by gamm. Tensor product smooths have a penalty matrix made up of a weighted sum of penalty matrices, where the weights are the smoothing parameters. In the mixed model formulation the penalty matrix is the inverse of the covariance matrix for the random effects of a term, and the smoothing parameters (times a half) are variance parameters to be estimated. It's not possible to transform the problem to make the required random effects covariance matrix look like one of the standard pdMat classes: hence the need for the pdTens class. A [notLog2](#) parameterization ensures that the parameters are positive.

These functions ([pdTens](#), [pdConstruct.pdTens](#), [pdFactor.pdTens](#), [pdMatrix.pdTens](#), [coef.pdTens](#) and [summary.pdTens](#)) would not normally be called directly.

**Usage**

```
pdTens(value = numeric(0), form = NULL,
 nam = NULL, data = sys.frame(sys.parent()))
```

**Arguments**

|              |                                                                                                                                                                                                                                            |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>value</b> | Initialization values for parameters. Not normally used.                                                                                                                                                                                   |
| <b>form</b>  | A one sided formula specifying the random effects structure. The formula should have an attribute S which is a list of the penalty matrices the weighted sum of which gives the inverse of the covariance matrix for these random effects. |
| <b>nam</b>   | a names argument, not normally used with this class.                                                                                                                                                                                       |
| <b>data</b>  | data frame in which to evaluate formula.                                                                                                                                                                                                   |

## Details

If using this class directly note that it is worthwhile scaling the S matrices to be of ‘moderate size’, for example by dividing each matrix by its largest singular value: this avoids problems with `lme` defaults (`smooth.construct.tensor.smooth.spec` does this automatically).

This appears to be the minimum set of functions required to implement a new `pdMat` class.

Note that while the `pdFactor` and `pdMatrix` functions return the inverse of the scaled random effect covariance matrix or its factor, the `pdConstruct` function is sometimes initialised with estimates of the scaled covariance matrix, and sometimes initialized with its inverse.

## Value

A class `pdTens` object, or its coefficients or the matrix it represents or the factor of that matrix. `pdFactor` returns the factor as a vector (packed column-wise) (`pdMatrix` always returns a matrix).

```

pen.edf

*Extract the effective degrees of freedom associated with each penalty in a gam fit*

## Description

Finds the coefficients penalized by each penalty and adds up their effective degrees of freedom. Very useful for `t2` terms, but hard to interpret for terms where the penalties penalize overlapping sets of parameters (e.g. `te` terms).

## Usage

```
pen.edf(x)
```

## Arguments

|   |                                            |
|---|--------------------------------------------|
| x | an object inheriting from <code>gam</code> |
|---|--------------------------------------------|

## Details

Useful for models containing [t2](#) terms, since it splits the EDF for the term up into parts due to different components of the smooth. This is useful for figuring out which interaction terms are actually needed in a model.

## Value

A vector of EDFs, named with labels identifying which penalty each EDF relates to.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

## See Also

[t2](#)

## Examples

```
require(mgcv)
set.seed(20)
dat <- gamSim(1,n=400,scale=2) ## simulate data
following 't2' smooth basically separates smooth
of x0,x1 into main effects + interaction....
b <- gam(y~t2(x0,x1,bs="tp",m=1,k=7)+s(x2)+s(x3),
 data=dat,method="ML")
pen.edf(b)

label "rr" indicates interaction edf (range space times range space)
label "nr" (null space for x0 times range space for x1) is main
effect for x1.
label "rn" is main effect for x0
clearly interaction is negligible

second example with higher order marginals.

b <- gam(y~t2(x0,x1,bs="tp",m=2,k=7,full=TRUE)
 +s(x2)+s(x3),data=dat,method="ML")
pen.edf(b)

In this case the EDF is negligible for all terms in the t2 smooth
apart from the 'main effects' (r2 and 2r). To understand the labels
consider the following 2 examples....
"r1" relates to the interaction of the range space of the first
marginal smooth and the first basis function of the null
space of the second marginal smooth
"2r" relates to the interaction of the second basis function of
the null space of the first marginal smooth with the range
space of the second marginal smooth.
```

|                          |                                                                           |
|--------------------------|---------------------------------------------------------------------------|
| <code>place.knots</code> | <i>Automatically place a set of knots evenly through covariate values</i> |
|--------------------------|---------------------------------------------------------------------------|

## Description

Given a univariate array of covariate values, places a set of knots for a regression spline evenly through the covariate values.

## Usage

```
place.knots(x,nk)
```

## Arguments

- x               array of covariate values (need not be sorted).
- nk              integer indicating the required number of knots.

## Details

Places knots evenly throughout a set of covariates. For example, if you had 11 covariate values and wanted 6 knots then a knot would be placed at the first (sorted) covariate value and every second (sorted) value thereafter. With less convenient numbers of data and knots the knots are placed within intervals between data in order to achieve even coverage, where even means having approximately the same number of data between each pair of knots.

## Value

An array of knot locations.

---

plot.gam*Default GAM plotting*

---

**Description**

Takes a fitted `gam` object produced by `gam()` and plots the component smooth functions that make it up, on the scale of the linear predictor. Optionally produces term plots for parametric model components as well.

**Usage**

```
S3 method for class 'gam'
plot(x, residuals=FALSE, rug=TRUE, se=TRUE, pages=0, select=NULL, scale=-1,
 n=100, n2=40, pers=FALSE, theta=30, phi=30, jit=FALSE, xlab=NULL,
 ylab=NULL, main=NULL, ylim=NULL, xlim=NULL, too.far=0.1,
 all.terms=FALSE, shade=FALSE, shade.col="gray80",
 shift=0, trans=I, seWithMean=FALSE, by.resids=FALSE,
 scheme=0, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | a fitted <code>gam</code> object as produced by <code>gam()</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>residuals</code> | If TRUE then partial residuals are added to plots of 1-D smooths. If FALSE then no residuals are added. If this is an array of the correct length then it is used as the array of residuals to be used for producing partial residuals. If TRUE then the residuals are the working residuals from the IRLS iteration weighted by the IRLS weights. Partial residuals for a smooth term are the residuals that would be obtained by dropping the term concerned from the model, while leaving all other estimates fixed (i.e. the estimates for the term plus the residuals). |
| <code>rug</code>       | when TRUE (default) then the covariate to which the plot applies is displayed as a rug plot at the foot of each plot of a 1-d smooth, and the locations of the covariates are plotted as points on the contour plot representing a 2-d smooth.                                                                                                                                                                                                                                                                                                                               |
| <code>se</code>        | when TRUE (default) upper and lower lines are added to the 1-d plots at 2 standard errors above and below the estimate of the smooth being plotted while for 2-d plots, surfaces at +1 and -1 standard errors are contoured and overlayed on the contour plot for the estimate. If a positive number is supplied then this number is multiplied by the standard errors when calculating standard error curves or surfaces. See also <code>shade</code> , below.                                                                                                              |
| <code>pages</code>     | (default 0) the number of pages over which to spread the output. For example, if <code>pages</code> =1 then all terms will be plotted on one page with the layout performed automatically. Set to 0 to have the routine leave all graphics settings as they are.                                                                                                                                                                                                                                                                                                             |
| <code>select</code>    | Allows the plot for a single model term to be selected for printing. e.g. if you just want the plot for the second smooth term set <code>select</code> =2.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>scale</code>     | set to -1 (default) to have the same y-axis scale for each plot, and to 0 for a different y axis for each plot. Ignored if <code>ylim</code> supplied.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>n</code>         | number of points used for each 1-d plot - for a nice smooth plot this needs to be several times the estimated degrees of freedom for the smooth. Default value 100.                                                                                                                                                                                                                                                                                                                                                                                                          |

|                   |                                                                                                                                                                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>n2</b>         | Square root of number of points used to grid estimates of 2-d functions for contouring.                                                                                                                                                                                                                                        |
| <b>pers</b>       | Set to TRUE if you want perspective plots for 2-d terms.                                                                                                                                                                                                                                                                       |
| <b>theta</b>      | One of the perspective plot angles.                                                                                                                                                                                                                                                                                            |
| <b>phi</b>        | The other perspective plot angle.                                                                                                                                                                                                                                                                                              |
| <b>jit</b>        | Set to TRUE if you want rug plots for 1-d terms to be jittered.                                                                                                                                                                                                                                                                |
| <b>xlab</b>       | If supplied then this will be used as the x label for all plots.                                                                                                                                                                                                                                                               |
| <b>ylab</b>       | If supplied then this will be used as the y label for all plots.                                                                                                                                                                                                                                                               |
| <b>main</b>       | Used as title (or z axis label) for plots if supplied.                                                                                                                                                                                                                                                                         |
| <b>ylim</b>       | If supplied then this pair of numbers are used as the y limits for each plot.                                                                                                                                                                                                                                                  |
| <b>xlim</b>       | If supplied then this pair of numbers are used as the x limits for each plot.                                                                                                                                                                                                                                                  |
| <b>too.far</b>    | If greater than 0 then this is used to determine when a location is too far from data to be plotted when plotting 2-D smooths. This is useful since smooths tend to go wild away from data. The data are scaled into the unit square before deciding what to exclude, and <b>too.far</b> is a distance within the unit square. |
| <b>all.terms</b>  | if set to TRUE then the partial effects of parametric model components are also plotted, via a call to <a href="#">termplot</a> . Only terms of order 1 can be plotted in this way.                                                                                                                                            |
| <b>shade</b>      | Set to TRUE to produce shaded regions as confidence bands for smooths (not available for parametric terms, which are plotted using <a href="#">termplot</a> ).                                                                                                                                                                 |
| <b>shade.col</b>  | define the color used for shading confidence bands.                                                                                                                                                                                                                                                                            |
| <b>shift</b>      | constant to add to each smooth (on the scale of the linear predictor) before plotting. Can be useful for some diagnostics, or with <b>trans</b> .                                                                                                                                                                              |
| <b>trans</b>      | function to apply to each smooth (after any shift), before plotting. <b>shift</b> and <b>trans</b> are occasionally useful as a means for getting plots on the response scale, when the model consists only of a single smooth.                                                                                                |
| <b>seWithMean</b> | if TRUE the component smooths are shown with confidence intervals that include the uncertainty about the overall mean. If FALSE then the uncertainty relates purely to the centred smooth itself. Marra and Wood (2012) suggests that TRUE results in better coverage performance, and this is also suggested by simulation.   |
| <b>by.resids</b>  | Should partial residuals be plotted for terms with <b>by</b> variables? Usually the answer is no, they would be meaningless.                                                                                                                                                                                                   |
| <b>scheme</b>     | Integer or integer vector selecting a plotting scheme for each plot. See details.                                                                                                                                                                                                                                              |
| <b>...</b>        | other graphics parameters to pass on to plotting commands.                                                                                                                                                                                                                                                                     |

## Details

Produces default plot showing the smooth components of a fitted GAM, and optionally parametric terms as well, when these can be handled by [termplot](#).

For smooth terms `plot.gam` actually calls `plot` method functions depending on the class of the smooth. Currently `random.effects`, Markov random fields (`mrf`), `Spherical.Spline` and `factor.smooth.interaction` terms have special methods (documented in their help files), the rest use the defaults described below.

For plots of 1-d smooths, the x axis of each plot is labelled with the covariate name, while the y axis is labelled `s(cov, edf)` where `cov` is the covariate name, and `edf` the estimated (or user defined for regression splines) degrees of freedom of the smooth. `scheme == 0` produces a smooth curve with dashed curves indicating 2 standard error bounds. `scheme == 1` illustrates the error bounds using a shaded region.

For `scheme==0`, contour plots are produced for 2-d smooths with the x-axes labelled with the first covariate name and the y axis with the second covariate name. The main title of the plot is something like `s(var1, var2, edf)`, indicating the variables of which the term is a function, and the estimated degrees of freedom for the term. When `se=TRUE`, estimator variability is shown by overlaying contour plots at plus and minus 1 s.e. relative to the main estimate. If `se` is a positive number then contour plots are at plus or minus `se` multiplied by the s.e. Contour levels are chosen to try and ensure reasonable separation of the contours of the different plots, but this is not always easy to achieve. Note that these plots can not be modified to the same extent as the other plot.

For 2-d smooths `scheme==1` produces a perspective plot, while `scheme==2` produces a heatmap, with overlaid contours.

Smooths of more than 2 variables are not plotted, but see [vis.gam](#).

Fine control of plots for parametric terms can be obtained by calling [termplot](#) directly, taking care to use its `terms` argument.

Note that, if `seWithMean=TRUE`, the confidence bands include the uncertainty about the overall mean. In other words although each smooth is shown centred, the confidence bands are obtained as if every other term in the model was constrained to have average 0, (average taken over the covariate values), except for the smooth concerned. This seems to correspond more closely to how most users interpret componentwise intervals in practice, and also results in intervals with close to nominal (frequentist) coverage probabilities by an extension of Nychka's (1988) results presented in Marra and Wood (2012).

Sometimes you may want a small change to a default plot, and the arguments to `plot.gam` just won't let you do it. In this case, the quickest option is sometimes to clone the `smooth.construct` and `Predict.matrix` methods for the smooth concerned, modifying only the returned smoother class (e.g. to `foo.smooth`). Then copy the `plot` method function for the original class (e.g. `mgcv:::plot.mgcv.smooth`), modify the source code to plot exactly as you want and rename the `plot` method function (e.g. `plot.foo.smooth`). You can then use the cloned smooth in models (e.g. `s(x, bs="foo")`), and it will automatically plot using the modified plotting function.

### Value

The function simply generates plots.

### WARNING

Note that the behaviour of this function is not identical to `plot.gam()` in S-PLUS.

Plots of 2-D smooths with standard error contours shown can not easily be customized.

The function can not deal with smooths of more than 2 variables!

### Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

Henric Nilsson <[henric.nilsson@statisticon.se](mailto:henric.nilsson@statisticon.se)> donated the code for the `shade` option.

The design is inspired by the `S` function of the same name described in Chambers and Hastie (1993) (but is not a clone).

**polys.plot***Plot geographic regions defined as polygons***Description**

Produces plots of geographic regions defined by polygons, optionally filling the polygons with a color or grey shade dependent on a covariate.

**Usage**

```
polys.plot(pc,z=NULL,scheme="heat",lab="",...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                             |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pc     | A named list of matrices. Each matrix has two columns. The matrix rows each define the vertex of a boundary polygon. If a boundary is defined by several polygons, then each of these must be separated by an NA row in the matrix. See <a href="#">mrf</a> for an example. |
| z      | A vector of values associated with each area (item) of pc. If the vector elements have names then these are used to match elements of z to areas defined in pc. Otherwise pc and z are assumed to be in the same order. If z is NULL then polygons are not filled.          |
| scheme | One of "heat" or "grey", indicating how to fill the polygons in accordance with the value of z.                                                                                                                                                                             |
| lab    | label for plot.                                                                                                                                                                                                                                                             |
| ...    | other arguments to pass to plot (currently only if z is NULL).                                                                                                                                                                                                              |

**Details**

Any polygon within another polygon counts as a hole in the area. Further nesting is dealt with by treating any point that is interior to an odd number of polygons as being within the area, and all other points as being exterior. The routine is provided to facilitate plotting with models containing [mrf](#) smooths.

**Value**

Simply produces a plot.

**predict.bam**

*Prediction from fitted Big Additive Model model*

## Description

Essentially a wrapper for [predict.gam](#) for prediction from a model fitted by [bam](#). Can compute on a parallel cluster.

Takes a fitted [bam](#) object produced by [bam](#) and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R (see example code below).

## Usage

```
S3 method for class 'bam'
predict(object,newdata,type="link",se.fit=FALSE,terms=NULL,
 block.size=50000,newdata.guaranteed=FALSE,na.action=na.pass,cluster=NULL,...)
```

## Arguments

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b>  | a fitted <a href="#">bam</a> object as produced by <a href="#">bam</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>newdata</b> | A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If newdata is provided then it should contain all the variables needed for prediction: a warning is generated if not.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>type</b>    | When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When type="terms" each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. type="iterms" is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When type="response" predictions on the scale of the response are returned (possibly with approximate standard errors). When type="lpmatrix" then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case se.fit is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below).                                                                                                                                                                                                                                               |
| se.fit             | when this is TRUE (not default) standard error estimates are returned for each prediction.                                                                                                                                                                                                                                                                                                                          |
| terms              | if type=="terms" then only results for the terms named in this array will be returned.                                                                                                                                                                                                                                                                                                                              |
| block.size         | maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive.                                                                                                                                                                                                                                                                                                 |
| newdata.guaranteed | Set to TRUE to turn off all checking of newdata except for sanity of factor levels: this can speed things up for large prediction tasks, but newdata must be complete, with no NA values for predictors required in the model.                                                                                                                                                                                      |
| na.action          | what to do about NA values in newdata. With the default na.pass, any row of newdata containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). na.exclude or na.omit result in the dropping of newdata rows, if they contain any NA values for required predictors. If newdata is missing then NA handling is determined from object\$na.action. |
| cluster            | predict.bam can compute in parallel using <a href="#">parLapply</a> from the <a href="#">parallel</a> package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code for <a href="#">bam</a> .                                                                                                                                  |
| ...                | other arguments.                                                                                                                                                                                                                                                                                                                                                                                                    |

## Details

The standard errors produced by predict.gam are based on the Bayesian posterior covariance matrix of the parameters  $V_p$  in the fitted bam object.

To facilitate plotting with [termplot](#), if object possesses an attribute "para.only" and type=="terms" then only parametric terms of order 1 are returned (i.e. those that [termplot](#) can handle).

Note that, in common with other prediction functions, any offset supplied to [gam](#) as an argument is always ignored when predicting, unlike offsets specified in the gam model formula.

See the examples in [predict.gam](#) for how to use the [lpmatrix](#) for obtaining credible regions for quantities derived from the model.

## Value

If type=="lpmatrix" then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if se.fit is TRUE then a 2 item list is returned with items (both arrays) fit and se.fit containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether type is "terms" or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

newdata can be a data frame, list or model.frame: if it's a model frame then all variables must be supplied.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

The design is inspired by the S function of the same name described in Chambers and Hastie (1993) (but is not a clone).

*predict.gam*

*Prediction from fitted GAM model*

**Description**

Takes a fitted `gam` object produced by `gam()` and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R (see example code below).

**Usage**

```
S3 method for class 'gam'
predict(object,newdata,type="link",se.fit=FALSE,terms=NULL,
 block.size=1000,newdata.guaranteed=FALSE,na.action=na.pass,...)
```

**Arguments**

- |         |                                                                                                                                                                                                                                                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | a fitted <code>gam</code> object as produced by <code>gam()</code> .                                                                                                                                                                                                                                                               |
| newdata | A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If <code>newdata</code> is provided then it should contain all the variables needed for prediction: a warning is generated if not. |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type               | When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When type="terms" each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. type="iterms" is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When type="response" predictions on the scale of the response are returned (possibly with approximate standard errors). When type="lpmatrix" then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case se.fit is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below). |
| se.fit             | when this is TRUE (not default) standard error estimates are returned for each prediction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| terms              | if type=="terms" then only results for the terms given in this array will be returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| block.size         | maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive. Set to < 1 to use total number of predictions as this.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| newdata.guaranteed | Set to TRUE to turn off all checking of newdata except for sanity of factor levels: this can speed things up for large prediction tasks, but newdata must be complete, with no NA values for predictors required in the model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| na.action          | what to do about NA values in newdata. With the default na.pass, any row of newdata containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). na.exclude or na.omit result in the dropping of newdata rows, if they contain any NA values for required predictors. If newdata is missing then NA handling is determined from object\$na.action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ...                | other arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Details

The standard errors produced by predict.gam are based on the Bayesian posterior covariance matrix of the parameters  $V_p$  in the fitted gam object.

To facilitate plotting with `termplot`, if `object` possesses an attribute "para.only" and type=="terms" then only parametric terms of order 1 are returned (i.e. those that `termplot` can handle).

Note that, in common with other prediction functions, any offset supplied to `gam` as an argument is always ignored when predicting, unlike offsets specified in the `gam` model formula.

See the examples for how to use the `lpmatrix` for obtaining credible regions for quantities derived from the model.

## Value

If type=="lpmatrix" then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector.

Otherwise, if `se.fit` is TRUE then a 2 item list is returned with items (both arrays) `fit` and `se.fit` containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether `type` is "terms" or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

`newdata` can be a data frame, list or `model.frame`: if it's a model frame then all variables must be supplied.

## WARNING

Note that the behaviour of this function is not identical to `predict.gam()` in Splus.

`type=="terms"` does not exactly match what `predict.lm` does for parametric model components.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

The design is inspired by the S function of the same name described in Chambers and Hastie (1993) (but is not a clone).

 t(mu + L%*%matrix(rnorm(m*n),m,n))
}

br <- rmvn(1000,coef(b),b$Vp) ## 1000 replicate param. vectors
res <- rep(0,1000)
for (i in 1:1000)
{ pr <- Xp %*% br[i,] ## replicate predictions
 res[i] <- sum(log(abs(pr))) ## example non-linear function
}
mean(res);var(res)

loop is replace-able by following

res <- colSums(log(abs(Xp %*% t(br)))))

#####
The following shows how to use use an "lpmatrix" as a lookup
table for approximate prediction. The idea is to create
approximate prediction matrix rows by appropriate linear
interpolation of an existing prediction matrix. The additivity
of a GAM makes this possible.
There is no reason to ever do this in R, but the following
code provides a useful template for predicting from a fitted
gam *outside* R: all that is needed is the coefficient vector
and the prediction matrix. Use larger 'Xp'/ smaller 'dx' and/or
higher order interpolation for higher accuracy.
#####

xn <- c(.341,.122,.476,.981) ## want prediction at these values
x0 <- 1 ## intercept column
dx <- 1/30 ## covariate spacing in 'newd'
for (j in 0:2) { ## loop through smooth terms
 cols <- 1+j*9 +1:9 ## relevant cols of Xp
 i <- floor(xn[j+1]*30) ## find relevant rows of Xp
 w1 <- (xn[j+1]-i*dx)/dx ## interpolation weights
 ## find approx. predict matrix row portion, by interpolation
 x0 <- c(x0,Xp[i+2,cols]*w1 + Xp[i+1,cols]*(1-w1))
}
dim(x0)<-c(1,28)
fv <- x0%*%coef(b) + xn[4];fv ## evaluate and add offset

```

```

se <- sqrt(x0%*%b$Vp%*%t(x0));se ## get standard error
compare to normal prediction
predict(b,newdata=data.frame(x0=xn[1],x1=xn[2],
 x2=xn[3],x3=xn[4]),se=TRUE)

 lines(x.mesh,df+2*df.sd,lty=2);lines(x.mesh,df-2*df.sd,lty=2)
}

```

## Description

Takes smooth objects produced by `smooth.construct` methods and obtains the matrix mapping the parameters associated with such a smooth to the predicted values of the smooth at a set of new covariate values.

In practice this method is often called via the wrapper function [PredictMat](#).

## Usage

```

Predict.matrix(object,data)
Predict.matrix2(object,data)

```

**Arguments**

- object** is a smooth object produced by a `smooth.construct` method function. The object contains all the information required to specify the basis for a term of its class, and this information is used by the appropriate `Predict.matrix` function to produce a prediction matrix for new covariate values. Further details are given in `smooth.construct`.
- data** A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for `smooth.construct` and `smooth.construct2`.

**Details**

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. The `Predict.matrix` functions are used to obtain the matrix that will map the parameters associated with a smooth term to the predicted values for the term at new covariate values.

Note that new smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function: see the example code provided for `smooth.construct` for details.

**Value**

A matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in `object`. If the smooth class is one which generates offsets the corresponding offset is returned as attribute "offset" of the matrix.

---

**Predict.matrix.cr.smooth***Predict matrix method functions*

---

**Description**

The various built in smooth classes for use with `gam` have associate `Predict.matrix` method functions to enable prediction from the fitted model.

**Usage**

```
S3 method for class 'cr.smooth'
Predict.matrix(object, data)
S3 method for class 'cs.smooth'
Predict.matrix(object, data)
S3 method for class 'cyclic.smooth'
Predict.matrix(object, data)
S3 method for class 'pspline.smooth'
Predict.matrix(object, data)
S3 method for class 'tensor.smooth'
Predict.matrix(object, data)
S3 method for class 'tprs.smooth'
Predict.matrix(object, data)
S3 method for class 'ts.smooth'
Predict.matrix(object, data)
```

**Arguments**

- |                     |                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a smooth object, usually generated by a <code>smooth.construct</code> method having processed a smooth specification object generated by an <code>s</code> or <code>te</code> term in a <code>gam</code> formula. |
| <code>data</code>   | A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for <code>smooth.construct</code> and <code>smooth.construct2</code> .        |

**Details**

The Predict matrix function is not normally called directly, but is rather used internally by `predict.gam` etc. to predict from a fitted `gam` model. See `Predict.matrix` for more details, or the specific `smooth.construct` pages for details on a particular smooth class.

**Value**

A matrix mapping the coefficients for the smooth term to its values at the supplied data values.

**Author(s)**

## Examples

```
see smooth.construct
```

---

Predict.matrix.soap.film

*Prediction matrix for soap film smooth*

---

## Description

Creates a prediction matrix for a soap film smooth object, mapping the coefficients of the smooth to the linear predictor component for the smooth. This is the `Predict.matrix` method function required by `gam`.

## Usage

```
S3 method for class 'soap.film'
Predict.matrix(object,data)
S3 method for class 'sw'
Predict.matrix(object,data)
S3 method for class 'sf'
Predict.matrix(object,data)
```

## Arguments

- `object` A class "soap.film", "sf" or "sw" object.  
`data` A list list or data frame containing the arguments of the smooth at which predictions are required.

## Details

The smooth object will be largely what is returned from `smooth.construct.so.smooth.spec`, although elements X and S are not needed, and need not be present, of course.

## Value

A matrix. This may have an "offset" attribute corresponding to the contribution from any known boundary conditions on the smooth.

**Examples**

```

This is a lower level example. The basis and
penalties are obtained explicitly
and 'magic' is used as the fitting routine...

require(mgcv)
set.seed(66)

create a boundary...
fsb <- list(fs.boundary())

create some internal knots...
knots <- data.frame(x=rep(seq(-.5,3,by=.5),4),
 y=rep(c(-.6,-.3,.3,.6),rep(8,4)))

Simulate some fitting data, inside boundary...
n<-1000
x <- runif(n)*5-1;y<-runif(n)*2-1
z <- fs.test(x,y,b=1)
ind <- inSide(fsb,x,y) ## remove outsiders
z <- z[ind];x <- x[ind]; y <- y[ind]
n <- length(z)
z <- z + rnorm(n)*.3 ## add noise

plot boundary with knot and data locations
plot(fsb[[1]]$x,fsb[[1]]$y,type="l");points(knots$x,knots$y,pch=20,col=2)
points(x,y,pch=". ",col=3);

set up the basis and penalties...
sob <- smooth.construct2(s(x,y,bs="so",k=40,xt=list(bnd=fsb,nmax=100)),
 data=data.frame(x=x,y=y),knots=knots)
... model matrix is element 'X' of sob, penalties matrices
are in list element 'S'.

fit using 'magic'
um <- magic(z,sob$X,sp=c(-1,-1),sob$S,off=c(1,1))
beta <- um$b

produce plots...
par(mfrow=c(2,2),mar=c(4,4,1,1))
m<-100;n<-50
xm <- seq(-1,3.5,length=m);yn<-seq(-1,1,length=n)
xx <- rep(xm,n);yy<-rep(yn,rep(m,n))

plot truth...
tru <- matrix(fs.test(xx,yy),m,n) ## truth
image(xm,yn,tru,col=heat.colors(100),xlab="x",ylab="y")
lines(fsb[[1]]$x,fsb[[1]]$y,lwd=3)
contour(xm,yn,tru,levels=seq(-5,5,by=.25),add=TRUE)

Plot soap, by first predicting on a fine grid...

```

```

First get prediction matrix...
X <- Predict.matrix2(sob,data=list(x=xx,y=yy))

Now the predictions...
fv <- X%*%beta

Plot the estimated function...
image(xm,yn,matrix(fv,m,n),col=heat.colors(100),xlab="x",ylab="y")
lines(fsb[[1]]$x,fsb[[1]]$y,lwd=3)
points(x,y,pch=".")
contour(xm,yn,matrix(fv,m,n),levels=seq(-5,5,by=.25),add=TRUE)

Plot TPRS...
b <- gam(z~s(x,y,k=100))
fv.gam <- predict(b,newdata=data.frame(x=xx,y=yy))
names(sobsdbnd[[1]]) <- c("xx","yy","d")
ind <- inSide(sobsdbnd,xx,yy)
fv.gam[!ind]<-NA
image(xm,yn,matrix(fv.gam,m,n),col=heat.colors(100),xlab="x",ylab="y")
lines(fsb[[1]]$x,fsb[[1]]$y,lwd=3)
points(x,y,pch=".")
contour(xm,yn,matrix(fv.gam,m,n),levels=seq(-5,5,by=.25),add=TRUE)

```

**print.gam***Print a Generalized Additive Model object.***Description**

The default print method for a `gam` object.

**Usage**

```

S3 method for class 'gam'
print(x, ...)

```

**Arguments**

`x, ...` fitted model objects of class `gam` as produced by `gam()`.

**Details**

Prints out the family, model formula, effective degrees of freedom for each smooth term, and optimized value of the smoothness selection criterion used. See [gamObject](#) (or `names(x)`) for a listing of what the object contains. [summary.gam](#) provides more detail.

Note that the optimized smoothing parameter selection criterion reported is one of GCV, UBRE(AIC), GACV, negative log marginal likelihood (ML), or negative log restricted likelihood (REML).

[gam](#), [summary.gam](#)

[qq.gam](#)

*QQ plots for gam model residuals*

## Description

Takes a fitted `gam` object produced by `gam()` and produces QQ plots of its residuals (conditional on the fitted model coefficients and scale parameter). If the model distributional assumptions are met then usually these plots should be close to a straight line (although discrete data can yield marked random departures from this line).

## Usage

```
qq.gam(object, rep=0, level=.9,s.rep=10,
 type=c("deviance","pearson","response"),
 pch=". ", r1.col=2, rep.col="gray80", ...)
```

## Arguments

|                      |                                                                                                                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | a fitted <code>gam</code> object as produced by <code>gam()</code> (or a <code>glm</code> object).                                                                                                                          |
| <code>rep</code>     | How many replicate datasets to generate to simulate quantiles of the residual distribution. 0 results in an efficient simulation free method for direct calculation, if this is possible for the object family.             |
| <code>level</code>   | If simulation is used for the quantiles, then reference intervals can be provided for the QQ-plot, this specifies the level. 0 or less for no intervals, 1 or more to simply plot the QQ plot for each replicate generated. |
| <code>s.rep</code>   | how many times to randomize uniform quantiles to data under direct computation.                                                                                                                                             |
| <code>type</code>    | what sort of residuals should be plotted? See <a href="#">residuals.gam</a> .                                                                                                                                               |

## Details

QQ-plots of the the model residuals can be produced in one of two ways. The cheapest method generates reference quantiles by associating a quantile of the uniform distribution with each datum, and feeding these uniform quantiles into the quantile function associated with each datum. The resulting quantiles are then used in place of each datum to generate approximate quantiles of residuals. The residual quantiles are averaged over `s.rep` randomizations of the uniform quantiles to data.

The second method is to use direct simulation. For each replicate, data are simulated from the fitted model, and the corresponding residuals computed. This is repeated `rep` times. Quantiles are readily obtained from the empirical distribution of residuals so obtained. From this method reference bands are also computable.

Even if `rep` is set to zero, the routine will attempt to simulate quantiles if no quantile function is available for the family. If no random deviate generating function family is available (e.g. for the quasi families), then a normal QQ-plot is produced. The routine conditions on the fitted model coefficents and the scale parameter estimate.

The plots are very similar to those proposed in Ben and Yohai (2004), but are substantially cheaper to produce (the interpretation of residuals for binary data in Ben and Yohai is not recommended).

Note that plots for raw residuals from fits to binary data contain almost no useful information about model fit. Whether the residual is negative or positive is decided by whether the response is zero or one. The magnitude of the residual, given its sign, is determined entirely by the fitted values. In consequence only the most gross violations of the model are detectable from QQ-plots of residuals for binary data. To really check distributional assumptions from residuals for binary data you have to be able to group the data somehow. Binomial models other than binary are ok.

plot(x,residuals(b),pch=19,cex=.3)
plot(b,residuals=TRUE,pch=19,cex=.3)

```

### Description

The smooth components of GAMs can be viewed as random effects for estimation purposes. This means that more conventional random effects terms can be incorporated into GAMs in two ways. The first method converts all the smooths into fixed and random components suitable for estimation

by standard mixed modelling software. Once the GAM is in this form then conventional random effects are easily added, and the whole model is estimated as a general mixed model. [gamm](#) and [gamm4](#) from the [gamm4](#) package operate in this way.

The second method represents the conventional random effects in a GAM in the same way that the smooths are represented — as penalized regression terms. This method can be used with [gam](#) by making use of `s(...,"re")` terms in a model: see [smooth.construct.re.smooth.spec](#). Alternatively, but less straightforwardly, the `paraPen` argument to [gam](#) can be used: see [gam.models](#). If smoothing parameter estimation is by ML or REML (e.g. `gam(...,method="REML")`) then this approach is a completely conventional likelihood based treatment of random effects.

[gam](#) can be slow for fitting models with large numbers of random effects, because it does not exploit the sparsity that is often a feature of parametric random effects. It can not be used for models with more coefficients than data. However [gam](#) is often faster and more reliable than [gamm](#) or [gamm4](#), when the number of random effects is modest.

To facilitate the use of random effects with [gam](#), [gam.vcomp](#) is a utility routine for converting smoothing parameters to variance components. It also provides confidence intervals, if smoothness estimation is by ML or REML.

Note that treating random effects as smooths does not remove the usual problems associated with testing variance components for equality to zero: see [summary.gam](#) and [anova.gam](#).

**residuals.gam***Generalized Additive Model residuals*

---

## Description

Returns residuals for a fitted `gam` model object. Pearson, deviance, working and response residuals are available.

## Usage

```
S3 method for class 'gam'
residuals(object, type = c("deviance", "pearson", "scaled.pearson",
 "working", "response"), ...)
```

## Arguments

- |                     |                                         |
|---------------------|-----------------------------------------|
| <code>object</code> | a <code>gam</code> fitted model object. |
| <code>type</code>   | the type of residuals wanted.           |
| <code>...</code>    | other arguments.                        |

## Details

Response residuals are the raw residuals (data minus fitted values). Scaled Pearson residuals are raw residuals divided by the standard deviation of the data according to the model mean variance relationship and estimated scale parameter. Pearson residuals are the same, but multiplied by the square root of the scale parameter (so they are independent of the scale parameter):  $((y - \mu) / \sqrt{V(\mu)})$ , where  $y$  is data  $\mu$  is model fitted value and  $V$  is model mean-variance relationship.). Both are provided since not all texts agree on the definition of Pearson residuals. Deviance residuals simply return the deviance residuals defined by the model family. Working residuals are the residuals returned from model fitting at convergence.

There is a special function for `gam` objects because of a bug in the calculation of Pearson residuals in some earlier versions of `residual.glm`.

## Value

An array of residuals.

| <code>rig</code> | <i>Generate inverse Gaussian random deviates</i> |
|------------------|--------------------------------------------------|

## Description

Generates inverse Gaussian random deviates.

## Usage

```
rig(n,mean,scale)
```

## Arguments

|                    |                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>n</code>     | the number of deviates required. If this has length > 1 then the length is taken as the number of deviates required. |
| <code>mean</code>  | vector of mean values.                                                                                               |
| <code>scale</code> | vector of scale parameter values (lambda, see below)                                                                 |

## Details

If  $x$  if the returned vector, then  $E(x) = \text{mean}$  while  $\text{var}(x) = \text{scale}^2 \times \text{mean}^3$ . For density and distribution functions see the `statmod` package. The algorithm used is Algorithm 5.7 of Gentle (2003), based on Michael et al. (1976). Note that `scale` here is the scale parameter in the GLM sense, which is the reciprocal of the usual ‘lambda’ parameter.

## Value

A vector of inverse Gaussian random deviates.

**rTweedie***Generate Tweedie random deviates***Description**

Generates Tweedie random deviates, for powers between 1 and 2.

**Usage**

```
rTweedie(mu, p=1.5, phi=1)
```

**Arguments**

|                  |                                                                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mu</code>  | vector of expected values for the deviates to be generated. One deviate generated for each element of <code>mu</code> .                                                                                              |
| <code>p</code>   | the variance of a deviate is proportional to its mean, <code>mu</code> to the power <code>p</code> . <code>p</code> must be between 1 and 2. 1 is Poisson like (exactly Poisson if <code>phi=1</code> ), 2 is gamma. |
| <code>phi</code> | The scale parameter. Variance of the deviates is given by <code>is phi*mu^p</code> .                                                                                                                                 |

**Details**

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution, with mean  $\mu^{(2-p)/((2-p)*\phi)}$ . The Gamma random variables that are summed have shape parameter  $(2-p)/(p-1)$  and scale parameter  $\phi*(p-1)*\mu^{(p-1)}$  (note that this scale parameter is different from the scale parameter for a GLM with Gamma errors).

This is a restricted, but faster, version of `rtweedie` from the `tweedie` package.

**Value**

A vector of random deviates from a Tweedie distribution, expected value vector `mu`, variance vector `phi*mu^p`.

```

s

*Defining smooths in GAM formulae*

## Description

Function used in definition of smooth terms within `gam` model formulae. The function does not evaluate a (spline) smooth - it exists purely to help set up a model using spline based smooths.

## Usage

```
s(..., k=-1, fx=FALSE, bs="tp", m=NA, by=NA, xt=NULL, id=NULL, sp=NULL)
```

## Arguments

|     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ... | a list of variables that are the covariates that this smooth is a function of.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| k   | the dimension of the basis used to represent the smooth term. The default depends on the number of variables that the smooth is a function of. k should not be less than the dimension of the null space of the penalty for the term (see <a href="#">null.space.dimension</a> ), but will be reset if it is. See <a href="#">choose.k</a> for further information.                                                                                                                                                                                                                                                                                               |
| fx  | indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| bs  | a two letter character string indicating the (penalized) smoothing basis to use. (eg "tp" for thin plate regression spline, "cr" for cubic regression spline). see <a href="#">smooth.terms</a> for an over view of what is available.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| m   | The order of the penalty for this term (e.g. 2 for normal cubic spline penalty with 2nd derivatives when using default t.p.r.s basis). NA signals autoinitilization. Only some smooth classes use this. The "ps" class can use a 2 item array giving the basis and penalty order separately.                                                                                                                                                                                                                                                                                                                                                                      |
| by  | a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth, evaluated at the corresponding covariate values (a 'varying coefficient model' results). For the numeric by variable case the resulting smooth is not usually subject to a centering constraint (so the by variable should not be added as an additional main effect). In the factor by variable case a replicate of the smooth is produced for each factor level (these smooths will be centered, so the factor usually needs to be added as a main effect as well). See <a href="#">gam.models</a> for further details. A by |

variable may also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see [gam.models](#) and [linear.functional.terms](#) for details).

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>xt</code> | Any extra information required to set up a particular basis. Used e.g. to set large data set handling behaviour for "tp" basis.                                                                                                                                                                                                                                                                                                                  |
| <code>id</code> | A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more terms have the same id then they will have the same smoothing paramsters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction). An id with a factor by variable causes the smooths at each factor level to have the same smoothing parameter. |
| <code>sp</code> | any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in <code>sp</code> argument to <a href="#">gam</a> . Ignored by <a href="#">gamm</a> .                                                                              |

## Details

The function does not evaluate the variable arguments. To use this function to specify use of your own smooths, note the relationships between the inputs and the output object and see the example in [smooth.construct](#).

## Value

A class `xx.smooth.spec` object, where `xx` is a basis identifying code given by the `bs` argument of `s`. These `smooth.spec` objects define smooths and are turned into bases and penalties by `smooth.construct` method functions.

The returned object contains the following items:

|                      |                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>term</code>    | An array of text strings giving the names of the covariates that the term is a function of.                                                                  |
| <code>bs.dim</code>  | The dimension of the basis used to represent the smooth.                                                                                                     |
| <code>fixed</code>   | TRUE if the term is to be treated as a pure regression spline (with fixed degrees of freedom); FALSE if it is to be treated as a penalized regression spline |
| <code>dim</code>     | The dimension of the smoother - i.e. the number of covariates that it is a function of.                                                                      |
| <code>p.order</code> | The order of the t.p.r.s. penalty, or 0 for auto-selection of the penalty order.                                                                             |
| <code>by</code>      | is the name of any by variable as text ("NA" for none).                                                                                                      |
| <code>label</code>   | A suitable text label for this smooth term.                                                                                                                  |
| <code>xt</code>      | The object passed in as argument <code>xt</code> .                                                                                                           |
| <code>id</code>      | An identifying label or number for the smooth, linking it to other smooths. Defaults to NULL for no linkage.                                                 |
| <code>sp</code>      | array of smoothing parameters for the term (negative for auto-estimation). Defaults to NULL.                                                                 |

## Examples

```
example utilising 'by' variables
library(mgcv)
set.seed(0)
n<-200;sig2<-4
x1 <- runif(n, 0, 1);x2 <- runif(n, 0, 1);x3 <- runif(n, 0, 1)
fac<-c(rep(1,n/2),rep(2,n/2)) # create factor
fac.1<-rep(0,n)+(fac==1);fac.2<-1-fac.1 # and dummy variables
fac<-as.factor(fac)
f1 <- exp(2 * x1) - 3.75887
f2 <- 0.2 * x1^11 * (10 * (1 - x1))^6 + 10 * (10 * x1)^3 * (1 - x1)^10
f<-f1*fac.1+f2*fac.2+x2
e <- rnorm(n, 0, sqrt(abs(sig2)))
y <- f + e
NOTE: smooths will be centered, so need to include fac in model....
b<-gam(y~fac+s(x1,by=fac)+x2)
plot(b, pages=1)
```

slanczos

*Compute truncated eigen decomposition of a symmetric matrix*

## Description

Uses Lanczos iteration to find the truncated eigen-decomposition of a symmetric matrix.

## Usage

```
slanczos(A,k=10,k1=-1,tol=.Machine$double.eps^.5)
```

## Arguments

- |    |                                                                                                                                                                                                                                                                                                               |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A  | A symmetric matrix.                                                                                                                                                                                                                                                                                           |
| k  | Must be non-negative. If k1 is negative, then the k largest magnitude eigenvalues are found, together with the corresponding eigenvectors. If k1 is non-negative then the k highest eigenvalues are found together with their eigenvectors and the k1 lowest eigenvalues with eigenvectors are also returned. |
| k1 | If k1 is non-negative then the k1 lowest eigenvalues are returned together with their corresponding eigenvectors (in addition to the k highest eigenvalues + vectors). negative k1 signals that the k largest magnitude eigenvalues should be returned, with eigenvectors.                                    |

**tol** tolerance to use for convergence testing of eigenvalues. Error in eigenvalues will be less than the magnitude of the dominant eigenvalue multiplied by **tol** (or the machine precision!).

## Details

If  $k_1$  is non-negative, returns the highest  $k$  and lowest  $k_1$  eigenvalues, with their corresponding eigenvectors. If  $k_1$  is negative, returns the largest magnitude  $k$  eigenvalues, with corresponding eigenvectors.

The routine implements Lanczos iteration with full re-orthogonalization as described in Demmel (1997). Lanczos iteration iteratively constructs a tridiagonal matrix, the eigenvalues of which converge to the eigenvalues of  $A$ , as the iteration proceeds (most extreme first). Eigenvectors can also be computed. For small  $k$  and  $k_1$  the approach is faster than computing the full symmetric eigendecomposition. The tridiagonal eigenproblems are handled using LAPACK.

The implementation is not optimal: in particular the inner triadiagonal problems could be handled more efficiently, and there would be some savings to be made by not always returning eigenvectors.

## Value

A list with elements **values** (array of eigenvalues); **vectors** (matrix with eigenvectors in its columns); **iter** (number of iterations required).

## Examples

```
require(mgcv)
create some x's and knots...
set.seed(1);
n <- 700;A <- matrix(runif(n*n),n,n);A <- A+t(A)

compare timings of slanczos and eigen
system.time(er <- slanczos(A,10))
system.time(um <- eigen(A,symmetric=TRUE))

confirm values are the same...
ind <- c(1:6,(n-3):n)
range(er$values-um$values[ind]);range(abs(er$vectors)-abs(um$vectors[,ind]))
```

---

**smooth.construct***Constructor functions for smooth terms in a GAM*

---

**Description**

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. New smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function (see example code below).

In practice, `smooth.construct` is usually called via `smooth.construct2` and the wrapper function `smoothCon`, in order to handle by variables and centering constraints (see the `smoothCon` documentation if you need to handle these things directly, for a user defined smooth class).

**Usage**

```
smooth.construct(object,data,knots)
smooth.construct2(object,data,knots)
```

**Arguments**

- object** is a smooth specification object, generated by an `s` or `te` term in a GAM formula. Objects generated by `s` terms have class `xx.smooth.spec` where `xx` is given by the `bs` argument of `s` (this convention allows the user to add their own smoothers). If `object` is not class `tensor.smooth.spec` it will have the following elements:
- term** The names of the covariates for this smooth, in an array.
  - bs.dim** Argument `k` of the `s` term generating the object. This is the dimension of the basis used to represent the term (or, arguably, 1 greater than the basis dimension for `cc` terms). `bs.dim < 0` indicates that the constructor should set this to the default value.
  - fixed** TRUE if the term is to be unpenalized, otherwise FALSE.
  - dim** the number covariates of which this smooth is a function.
  - p.order** the order of the smoothness penalty or NA for autoselection of this. This is argument `m` of the `s` term that generated object.
  - by** the name of any by variable to multiply this term as supplied as an argument to `s`. "NA" if there is no such term.
  - label** A suitable label for use with this term.
  - xt** An object containing information that may be needed for basis setup (used, e.g. by "tp" smooths to pass optional information on big dataset handling).
  - id** Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.
  - sp** Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides `sp` argument to `gam`.

If `object` is of class `tensor.smooth.spec` then it was generated by a `te` term in the GAM formula, and specifies a smooth of several variables with a basis generated as a tensor product of lower dimensional bases. In this case the object will be different and will have the following elements:

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>margin</b> | is a list of smooth specification objects of the type listed above, defining the bases which have their tensor product formed in order to construct this term.                                                                                                                                                                                                                                                                                                                    |
| <b>term</b>   | is the array of names of the covariates that are arguments of the smooth.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>by</b>     | is the name of any by variable, or "NA".                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>fx</b>     | is an array, the elements of which indicate whether (TRUE) any of the margins in the tensor product should be unpenalized.                                                                                                                                                                                                                                                                                                                                                        |
| <b>label</b>  | A suitable label for use with this term.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>dim</b>    | is the number of covariates of which this smooth is a function.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>mp</b>     | TRUE if multiple penalties are to be used.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>np</b>     | TRUE if 1-D marginal smooths are to be re-parameterized in terms of function values.                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>id</b>     | Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.                                                                                                                                                                                                                                                                                                                                                 |
| <b>sp</b>     | Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides sp argument to <code>gam</code> .                                                                                                                                                                                                                                                                                                |
| <b>data</b>   | For <code>smooth.construct</code> a data frame or list containing the evaluation of the elements of <code>object\$term</code> , with names given by <code>object\$term</code> . The last entry will be the by variable, if <code>object\$by</code> is not "NA". For <code>smooth.construct2</code> data need only be an object within which <code>object\$term</code> can be evaluated, the variables can be in any order, and there can be irrelevant variables present as well. |
| <b>knots</b>  | an optional data frame or list containing the knots relating to <code>object\$term</code> . If it is NULL then the knot locations are generated automatically. The structure of knots should be as for data, depending on whether <code>smooth.construct</code> or <code>smooth.construct2</code> is used.                                                                                                                                                                        |

## Details

There are built in methods for objects with the following classes: `tp.smooth.spec` (thin plate regression splines: see [tprs](#)); `ts.smooth.spec` (thin plate regression splines with shrinkage-to-zero); `cr.smooth.spec` (cubic regression splines: see [cubic.regression.spline](#)); `cs.smooth.spec` (cubic regression splines with shrinkage-to-zero); `cc.smooth.spec` (cyclic cubic regression splines); `ps.smooth.spec` (Eilers and Marx (1986) style P-splines: see [p.spline](#)); `cp.smooth.spec` (cyclic P-splines); `ad.smooth.spec` (adaptive smooths of 1 or 2 variables: see [adaptive.smooth](#)); `re.smooth.spec` (simple random effect terms); `mrf.smooth.spec` (Markov random field smoothers for smoothing over discrete districts); `tensor.smooth.spec` (tensor product smooths).

There is an implicit assumption that the basis only depends on the knots and/or the set of unique covariate combinations; i.e. that the basis is the same whether generated from the full set of covariates, or just the unique combinations of covariates.

Plotting of smooths is handled by plot methods for smooth objects. A default `mgcv.smooth` method is used if there is no more specific method available. Plot methods can be added for specific smooth classes, see source code for `mgcv:::plot.sos.smooth`, `mgcv:::plot.random.effect`, `mgcv:::plot.mgcv.smooth` for example code.

## Value

The input argument `object`, assigned a new class to indicate what type of smooth it is and with at least the following items added:

|                             |                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X                           | The model matrix from this term. This may have an "offset" attribute: a vector of length <code>nrow(X)</code> containing any contribution of the smooth to the model offset term. <code>by</code> variables do not need to be dealt with here, but if they are then an item <code>by.done</code> must be added to the object. |
| S                           | A list of positive semi-definite penalty matrices that apply to this term. The list will be empty if the term is to be left un-penalized.                                                                                                                                                                                     |
| rank                        | An array giving the ranks of the penalties.                                                                                                                                                                                                                                                                                   |
| <code>null.space.dim</code> | The dimension of the penalty null space (before centering).                                                                                                                                                                                                                                                                   |

The following items may be added:

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| C                           | The matrix defining any identifiability constraints on the term, for use when fitting. If this is <code>NULL</code> then <code>smoothCon</code> will add an identifiability constraint that each term should sum to zero over the covariate values. Set to a zero row matrix if no constraints are required. If a supplied <code>C</code> has an attribute " <code>always.apply</code> " then it is never ignored, even if any <code>by</code> variables of a smooth imply that no constraint is actually needed. |
| <code>Cp</code>             | An optional matrix supplying alternative identifiability constraints for use when predicting. By default the fitting constraints are used. This option is useful when some sort of simple sparse constraint is required for fitting, but the usual sum-to-zero constraint is required for prediction so that, e.g. the CIs for model components are as narrow as possible.                                                                                                                                        |
| <code>no.rescale</code>     | if this is non- <code>NULL</code> then the penalty coefficient matrix of the smooth will not be rescaled for enhanced numerical stability (rescaling is the default, because <code>gamm</code> requires it). Turning off rescaling is useful if the values of the smoothing parameters should be interpretable in a model, for example because they are inverse variance components.                                                                                                                              |
| <code>df</code>             | the degrees of freedom associated with this term (when unpenalized and unconstrained). If this is <code>null</code> then <code>smoothCon</code> will set it to the basis dimension. <code>smoothCon</code> will reduce this by the number of constraints.                                                                                                                                                                                                                                                         |
| <code>te.ok</code>          | 0 if this term should not be used as a tensor product marginal, 1 if it can be used and plotted, and 2 if it can be used but not plotted. Set to 1 if <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                         |
| <code>plot.me</code>        | Set to <code>FALSE</code> if this smooth should not be plotted by <code>plot.gam</code> . Set to <code>TRUE</code> if <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                         |
| <code>side.constrain</code> | Set to <code>FALSE</code> to ensure that the smooth is never subject to side constraints as a result of nesting.                                                                                                                                                                                                                                                                                                                                                                                                  |
| L                           | smooths may depend on fewer 'underlying' smoothing parameters than there are elements of S. In this case L is the matrix mapping the vector of underlying log smoothing parameters to the vector of logs of the smoothing parameters actually multiplying the S[[i]]. L=NULL signifies that there is one smoothing parameter per S[[i]].                                                                                                                                                                          |

Usually the returned object will also include extra information required to define the basis, and used by `Predict.matrix` methods to make predictions using the basis. See the Details section for links to the information included for the built in smooth classes.

`tensor.smooth` returned objects will additionally have each element of the `margin` list updated in the same way. `tensor.smooths` also have a list, `XP`, containing re-parameterization matrices for any 1-D marginal terms re-parameterized in terms of function values. This list will have `NULL` entries for marginal smooths that are not re-parameterized, and is only long enough to reach the last re-parameterized marginal in the list.

## WARNING

User defined smooth objects should avoid having attributes names "qrc" or "nCons" as these are used internally to provide constraint free parameterizations.

```

**smooth.construct.ad.smooth.spec***Adaptive smooths in GAMs***Description**

**gam** can use adaptive smooths of one or two variables, specified via terms like `s(...,bs="ad",...)`. (**gamm** can not use such terms — check out package **AdaptFit** if this is a

problem.) The basis for such a term is a (tensor product of) p-spline(s) or cubic regression spline(s). Discrete P-spline type penalties are applied directly to the coefficients of the basis, but the penalties themselves have a basis representation, allowing the strength of the penalty to vary with the covariates. The coefficients of the penalty basis are the smoothing parameters.

When invoking an adaptive smoother the `k` argument specifies the dimension of the smoothing basis (default 40 in 1D, 15 in 2D), while the `m` argument specifies the dimension of the penalty basis (default 5 in 1D, 3 in 2D). For an adaptive smooth of two variables `k` is taken as the dimension of both marginal bases: different marginal basis dimensions can be specified by making `k` a two element vector. Similarly, in the two dimensional case `m` is the dimension of both marginal bases for the penalties, unless it is a two element vector, which specifies different basis dimensions for each marginal (If the penalty basis is based on a thin plate spline then `m` specifies its dimension directly).

By default, P-splines are used for the smoothing and penalty bases, but this can be modified by supplying a list as argument `xt` with a character vector `xt$bs` specifying the smoothing basis type. Only "ps", "cp", "cc" and "cr" may be used for the smoothing basis. The penalty basis is always a B-spline, or a cyclic B-spline for cyclic bases.

The total number of smoothing parameters to be estimated for the term will be the dimension of the penalty basis. Bear in mind that adaptive smoothing places quite severe demands on the data. For example, setting `m=10` for a univariate smooth of 200 data is rather like estimating 10 smoothing parameters, each from a data series of length 20. The problem is particularly serious for smooths of 2 variables, where the number of smoothing parameters required to get reasonable flexibility in the penalty can grow rather fast, but it often requires a very large smoothing basis dimension to make good use of this flexibility. In short, adaptive smooths should be used sparingly and with care.

In practice it is often as effective to simply transform the smoothing covariate as it is to use an adaptive smooth.

## Usage

```
S3 method for class 'ad.smooth.spec'
smooth.construct(object, data, knots)
```

## Arguments

|                     |                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a smooth specification object, usually generated by a term <code>s(...,bs="ad",...)</code>                                                                                                                    |
| <code>data</code>   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| <code>knots</code>  | a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code> .                                                                    |

## Details

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

This class can not be used as a marginal basis in a tensor product smooth, nor by `gamm`.

## Value

An object of class "pspline.smooth" in the 1D case or "tensor.smooth" in the 2D case.

vis.gam(b1,theta=30,phi=30,ticktype="detailed")
```

```
Now adaptive...
b <- gam(y~s(x,z,bs="ad",k=15,m=3),gamma=1.4)
vis.gam(b,theta=30,phi=30,ticktype="detailed")
cor(fitted(b0),f);cor(fitted(b),f)
```

**smooth.construct.cr.smooth.spec***Penalized Cubic regression splines in GAMs***Description**

`gam` can use univariate penalized cubic regression spline smooths, specified via terms like `s(x,bs="cr")`. `s(x,bs="cs")` specifies a penalized cubic regression spline which has had its penalty modified to shrink towards zero at high enough smoothing parameters (as the smoothing parameter goes to infinity a normal cubic spline tends to a straight line.) `s(x,bs="cc")` specifies a cyclic penalized cubic regression spline smooth.

'Cardinal' spline bases are used: Wood (2006) sections 4.1.2 and 4.1.3 gives full details. These bases have very low setup costs. For a given basis dimension, k, they typically perform a little less well than thin plate regression splines, but a little better than p-splines. See `te` to use these bases in tensor product smooths of several variables.

Default k is 10.

**Usage**

```
S3 method for class 'cr.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'cs.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'cc.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

- |                     |                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a smooth specification object, usually generated by a term <code>s(...,bs="cr",...)</code> , <code>s(...,bs="cs",...)</code> or <code>s(...,bs="cc",...)</code>                                               |
| <code>data</code>   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| <code>knots</code>  | a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code> . See details.                                                       |

**Details**

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

If they are not supplied then the knots of the spline are placed evenly throughout the covariate values to which the term refers: For example, if fitting 101 data with an 11 knot spline of x then there would

be a knot at every 10th (ordered)  $x$  value. The parameterization used represents the spline in terms of its values at the knots. The values at neighbouring knots are connected by sections of cubic polynomial constrained to be continuous up to and including second derivative at the knots. The resulting curve is a natural cubic spline through the values at the knots (given two extra conditions specifying that the second derivative of the curve should be zero at the two end knots).

The shrinkage version of the smooth, eigen-decomposes the wigginess penalty matrix, and sets its 2 zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

Note that the cyclic smoother will wrap at the smallest and largest covariate values, unless knots are supplied. If only two knots are supplied then they are taken as the end points of the smoother (provided all the data lie between them), and the remaining knots are generated automatically.

The cyclic smooth is not subject to the condition that second derivatives go to zero at the first and last knots.

### Value

An object of class "cr.smooth" "cs.smooth" or "cyclic.smooth". In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

- xp giving the knot locations used to generate the basis.
- BD class "cyclic.smooth" objects include matrix BD which transforms function values at the knots to second derivatives at the knots.

```

```
plot(b,select=2,shade=TRUE);plot(fitted(b),residuals(b))
```

## smooth.construct.ds.smooth.spec

### *Low rank Duchon 1977 splines*

## Description

Thin plate spline smoothers are a special case of the isotropic splines discussed in Duchon (1977). A subset of this more general class can be invoked by terms like `s(x, z, bs="ds", m=c(1, .5)` in a `gam` model formula. In the notation of Duchon (1977) `m` is given by `m[1]` (default value 2), while `s` is given by `m[2]` (default value 0).

Duchon's (1977) construction generalizes the usual thin plate spline penalty as follows. The usual TPS penalty is given by the integral of the squared Euclidian norm of a vector of mixed partial derivatives of the function w.r.t. its arguments. Duchon re-expresses this penalty in the Fourier domain, and then weights the squared norm in the integral by the Euclidean norm of the fourier frequencies, raised to the power `2s`. `s` is a user selected constant taking integer values divided by 2. If `d` is the numberof arguments of the smooth, then it is required that  $-d/2 < s < d/2$ . To obtain continuous functions we further require that  $m + s > d/2$ . If `s=0` then the usual thin plate spline is recovered.

The construction is amenable to exactly the low rank approximation method given in Wood (2003) to thin plate splines, with similar optimality properties, so this approach to low rank smoothing is used here. For large datasets the same subsampling approach as is used in the `tprs` case is employed here to reduce computational costs.

These smoothers allow the use of lower orders of derivative in the penalty than conventional thin plate splines, while still yielding continuous functions.

## Usage

```
S3 method for class 'ds.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'duchon.spline'
Predict.matrix(object, data)
```

## Details

The default basis dimension for this class is  $k=M+k\text{.def}$  where  $M$  is the null space dimension (dimension of unpenalized function space) and  $k\text{.def}$  is 10 for dimension 1, 30 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by [gam](#). To use for basis setup it is recommended to use [smooth.construct2](#).

For these classes the specification object will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 ‘knots’ from which to produce a reduced rank eigen approximation to the full basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to [s](#). This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing). Note that the random sampling will not effect the state of R’s RNG.

For these bases `knots` has two uses. Firstly, as mentioned already, for large datasets the calculation of the `tp` basis can be time-consuming. The user can retain most of the advantages of the approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension,  $k$ . This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension,  $k$ . For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

## Value

An object of class “`duchon.spline`”. In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

|                                   |                                                                                                                                                                                               |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>shift</code>                | A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term. |
| <code>Xu</code>                   | A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).                                                          |
| <code>UZ</code>                   | The matrix mapping the smoother parameters back to the parameters of a full Duchon spline.                                                                                                    |
| <code>null.space.dimension</code> | The dimension of the space of functions that have zero wigginess according to the wigginess penalty for this term.                                                                            |

## smooth.construct.fs.smooth.spec

### *Factor smooth interactions in GAMs*

## Description

Simple factor smooth interactions, which are efficient when used with [gamm](#). This smooth class allows a separate smooth for each level of a factor, with the same smoothing parameter for all smooths. It is an alternative to using factor by variables.

See the discussion of by variables in [gam.models](#) for more general alternatives for factor smooth interactions (including interactions of tensor product smooths with factors).

## Usage

```
S3 method for class 'fs.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'fs.interaction'
Predict.matrix(object, data)
```

## Arguments

- |        |                                                                                                                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | For the <code>smooth.construct</code> method a smooth specification object, usually generated by a term <code>s(x, ..., bs="fs", )</code> . For the <code>predict.Matrix</code> method an object of class "fs.interaction" produced by the <code>smooth.construct</code> method. |
| data   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> .                                                                                                                                       |
| knots  | a list containing any knots supplied for smooth basis setup.                                                                                                                                                                                                                     |

## Details

This class produces a smooth for each level of a single factor variable. Within a [gam](#) formula this is done with something like `s(x, fac, bs="fs")`, which is almost equivalent to `s(x, by=fac, id=1)` (with the `gam` argument `select=TRUE`). The terms are fully penalized, with separate penalties on each null space component: for this reason they are not centred (no sum-to-zero constraint).

The class is particularly useful for use with [gamm](#), where estimation efficiently exploits the nesting of the smooth within the factor. Note however that: i) `gamm` only allows one conditioning factor for smooths, so `s(x)+s(z, fac, bs="fs") + s(v, fac, bs="fs")` is OK, but `s(x)+s(z, fac1, bs="fs") + s(v, fac2, bs="fs")` is not; ii) all additional random effects and correlation structures will be treated as nested within the factor of the smooth factor interaction.

Note that `gamm4` from the `gamm4` package suffers from none of the restrictions that apply to `gamm`, and "fs" terms can be used without side-effects.

Any singly penalized basis can be used to smooth at each factor level. The default is "tp", but alternatives can be supplied in the `xt` argument of `s` (e.g. `s(x, fac, bs="fs", xt="cr")` or `s(x, fac, bs="fs", xt=list(bs="cr"))`). The `k` argument to `s(..., bs="fs")` refers to the basis dimension to use for each level of the factor variable.

Note one computational bottleneck: currently [gamm](#) (or `gamm4`) will produce the full posterior covariance matrix for the smooths, including the smooths at each level of the factor. This matrix can get large and computationally costly if there are more than a few hundred levels of the factor. Even at one or two hundred levels, care should be taken to keep down `k`.

The plot method for this class has two schemes. `scheme==0` is in colour, while `scheme==1` is black and white.

## Value

An object of class "fs.interaction" or a matrix mapping the coefficients of the factor smooth interaction to the smooths themselves.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

## See Also

[gam.models](#), [gamm](#)

## Examples

```
library(mgcv)
set.seed(0)
simulate data...
f0 <- function(x) 2 * sin(pi * x)
f1 <- function(x,a=2,b=-1) exp(a * x)+b
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
 (10 * x)^3 * (1 - x)^10
n <- 500;nf <- 25
fac <- sample(1:nf,n,replace=TRUE)
x0 <- runif(n);x1 <- runif(n);x2 <- runif(n)
a <- rnorm(nf)*.2 + 2;b <- rnorm(nf)*.5
f <- f0(x0) + f1(x1,a[fac],b[fac]) + f2(x2)
fac <- factor(fac)
y <- f + rnorm(n)*2
```

```

so response depends on global smooths of x0 and
x2, and a smooth of x1 for each level of fac.

fit model...
bm <- gamm(y~s(x0)+ s(x1,fac,bs="fs",k=5)+s(x2,k=20))
plot(bm$gam, pages=1)

Could also use...
b <- gam(y~s(x0)+ s(x1,fac,bs="fs",k=5)+s(x2,k=20),method="ML")
... but its slower (increasingly so with increasing nf)
b <- gam(y~s(x0)+ t2(x1,fac,bs=c("tp","re"),k=5,full=TRUE) +
s(x2,k=20),method="ML")
... is exactly equivalent.

```

**smooth.construct.mrf.smooth.spec**  
*Markov Random Field Smooths*

### Description

For data observed over discrete spatial units, a simple Markov random field smoother is sometimes appropriate. These functions provide such a smoother class for mgcv.

### Usage

```

S3 method for class 'mrf.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'mrf.smooth'
Predict.matrix(object, data)

```

### Arguments

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b> | For the <code>smooth.construct</code> method a smooth specification object, usually generated by a term <code>s(x, ..., bs="mrf", xt=list(polys=foo))</code> . <code>x</code> is a factor variable giving labels for geographic districts, and the <code>xt</code> argument is obligatory: see details. For the <code>Predict.Matrix</code> method an object of class "mrf.smooth" produced by the <code>smooth.construct</code> method. |
| <b>data</b>   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element.                                                                                                                                                                                                                            |
| <b>knots</b>  | If there are more geographic areas than data were observed for, then this argument is used to provide the labels for all the areas (observed and unobserved).                                                                                                                                                                                                                                                                            |

### Details

A Markov random field smooth over a set of discrete areas is defined using a set of area labels, and a neighbourhood structure for the areas. The covariate of the smooth is the vector of area labels corresponding to each observation. This covariate should be a factor, or capable of being coerced to a factor.

The neighbourhood structure is supplied in the `xt` argument to `s`. This must contain at least one of the elements `polys`, `nb` or `penalty`.

**polys** contains the polygons defining the geographic areas. It is a list with as many elements as there are geographic areas. `names(polys)` must correspond to the levels of the argument of the `smooth`, in any order (i.e. it gives the area labels). `polys[[i]]` is a 2 column matrix the rows of which specify the vertices of the polygon(s) defining the boundary of the *i*th area. A boundary may be made up of several closed loops: these must be separated by NA rows. A polygon within another is treated as a hole. The first polygon in any `polys[[i]]` should not be a hole. An example of the structure is provided by `columb.polys` (which contains an artificial hole in its second element, for illustration). Any list elements with duplicate names are combined into a single NA separated matrix.

Plotting of the `smooth` is not possible without a `polys` object.

If `polys` is the only element of `xt` provided, then the neighbourhood structure is computed from it automatically. To count as neighbours, polygons must exactly share one of more vertices.

**nb** is a named list defining the neighbourhood structure. `names(nb)` must correspond to the levels of the covariate of the `smooth` (i.e. the area labels), but can be in any order. `nb[[i]]` is a vector indexing the neighbours of the *i*th area. All indices are relative to `nb` itself, but can be translated using `names(nb)`.

If no penalty is provided then it is computed automatically from this list. The *i*th row of the penalty matrix will be zero everywhere, except in the *i*th column, which will contain the number of neighbours of the *i*th geographic area, and the columns corresponding to those geographic neighbours, which will each contain -1.

**penalty** if this is supplied, then it is used as the penalty matrix. It should be positive semi-definite. Its row and column names should correspond to the levels of the covariate.

If no basis dimension is supplied then the constructor produces a full rank MRF, with a coefficient for each geographic area. Otherwise a low rank approximation is obtained based on truncation of the parameterization given in Wood (2006) Section 4.10.4.

Note that smooths of this class have a built in plot method, and that the utility function `in.out` can be useful for working with discrete area data. The plot method has two schemes, `scheme==0` is colour, `scheme==1` is grey scale.

## Value

An object of class "mrf.smooth" or a matrix mapping the coefficients of the MRF smooth to the predictions for the areas listed in `data`.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)> and Thomas Kneib (Fabian Scheipl prototyped the low rank MRF idea)

polys.plot(columb.polys,fv)

```

## smooth.construct.ps.smooth.spec

### *P-splines in GAMs*

## Description

`gam` can use univariate P-splines as proposed by Eilers and Marx (1996), specified via terms like `s(x,bs="ps")`. These terms use B-spline bases penalized by discrete penalties applied directly to the basis coefficients. Cyclic P-splines are specified by model terms like `s(x,bs="cp",...)`. These bases can be used in tensor product smooths (see [te](#)).

The advantage of P-splines is the flexible way that penalty and basis order can be mixed. This often provides a useful way of ‘taming’ an otherwise poorly behave smooth. However, in regular use, splines with derivative based penalties (e.g. “tp” or “cr” bases) tend to result in slightly better MSE performance, presumably because the good approximation theoretic properties of splines are rather closely connected to the use of derivative penalties.

## Usage

```

S3 method for class 'ps.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'cp.smooth.spec'
smooth.construct(object, data, knots)

```

## Arguments

|        |                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------|
| object | a smooth specification object, usually generated by a term <code>s(x,bs="ps",...)</code> or <code>s(x,bs="cp",...)</code> |
|--------|---------------------------------------------------------------------------------------------------------------------------|

|       |                                                                                                                                                                                                               |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data  | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| knots | a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL. See details for further information.                                                           |

## Details

A smooth term of the form `s(x, bs="ps", m=c(2, 3))` specifies a 2nd order P-spline basis (cubic spline), with a third order difference penalty (0th order is a ridge penalty) on the coefficients. If `m` is a single number then it is taken as the basis order and penalty order. The default is the ‘cubic spline like’ `m=c(2, 2)`.

The default basis dimension, `k`, is the larger of 10 and `m[1]+1` for a “ps” terms and the larger of 10 and `m[1]` for a “cp” term. `m[1]+1` and `m[1]` are the lower limits on basis dimension for the two types.

If knots are supplied, then the number of knots should be one more than the basis dimension (i.e. `k+1`) for a “cp” smooth. For the “ps” basis the number of supplied knots should be `k + m[1] + 2`, and the range of the middle `k-m[1]` knots should include all the covariate values. See example.

Alternatively, for both types of smooth, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (Don’t make this range too wide, however, or you can end up with no information about some basis coefficients, because the corresponding basis functions have a span that includes no data!). Note that P-splines don’t make much sense with uneven knot spacing.

Linear extrapolation is used for prediction that requires extrapolation (i.e. prediction outside the range of the interior `k-m[1]` knots). Such extrapolation is not allowed in basis construction, but is when predicting.

## Value

An object of class “ps.smooth” or “cp.smooth”. See `smooth.construct`, for the elements that this object will contain.

plot(b,select=1,shade=TRUE);lines(x,f-mean(f),col=2)
plot(b,select=2,shade=TRUE);lines(z,0*z,col=2)
plot(bk,select=1,shade=TRUE);lines(x,f-mean(f),col=2)
plot(bk,select=2,shade=TRUE);lines(z,0*z,col=2)

```

**smooth.construct.re.smooth.spec***Simple random effects in GAMs***Description**

`gam` can deal with simple independent random effects, by exploiting the link between smooths and random effects to treat random effects as smooths. `s(x,bs="re")` implements this. Such terms can have any number of predictors, which can be any mixture of numeric or factor variables. The terms produce a parametric interaction of the predictors, and penalize the corresponding coefficients with a multiple of the identity matrix, corresponding to an assumption of i.i.d. normality. See details.

**Usage**

```

S3 method for class 're.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'random.effect'
Predict.matrix(object, data)

```

**Arguments**

- |                     |                                                                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | For the <code>smooth.construct</code> method a smooth specification object, usually generated by a term <code>s(x,...,bs="re",)</code> . For the <code>predict.Matrix</code> method an object of class "random.effect" produced by the <code>smooth.construct</code> method. |
| <code>data</code>   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element.                                                                |
| <code>knots</code>  | generically a list containing any knots supplied for basis setup — unused at present.                                                                                                                                                                                        |

## Details

Exactly how the random effects are implemented is best seen by example. Consider the model term `s(x, z, bs="re")`. This will result in the model matrix component corresponding to  $\sim x:z-1$  being added to the model matrix for the whole model. The coefficients associated with the model matrix component are assumed i.i.d. normal, with unknown variance (to be estimated). This assumption is equivalent to an identity penalty matrix (i.e. a ridge penalty) on the coefficients. Because such a penalty is full rank, random effects terms do not require centering constraints.

If the nature of the random effect specification is not clear, consider a couple more examples: `s(x, bs="re")` results in `model.matrix(~x-1)` being appended to the overall model matrix, while `s(x, v, w, bs="re")` would result in `model.matrix(~x:v:w-1)` being appended to the model matrix. In both cases the corresponding model coefficients are assumed i.i.d. normal, and are hence subject to ridge penalties.

Note that smooth `ids` are not supported for random effect terms. Unlike most smooth terms, side conditions are never applied to random effect terms in the event of nesting (since they are identifiable without side conditions).

Random effects implemented in this way do not exploit the sparse structure of many random effects, and may therefore be relatively inefficient for models with large numbers of random effects, when `gamm4` or `gamm` may be better alternatives. Note also that `gam` will not support models with more coefficients than data.

## Value

An object of class "random.effect" or a matrix mapping the coefficients of the random effect to the random effects themselves.

---

`smooth.construct.so.smooth.spec`  
*Soap film smoother constructer*

---

## Description

Sets up basis functions and wigginess penalties for soap film smoothers (Wood, Bravington and Hedley, 2008). Soap film smoothers are based on the idea of constructing a 2-D smooth as a film of soap connecting a smoothly varying closed boundary. Unless smoothing very heavily, the film is distorted towards the data. The smooths are designed not to smooth across boundary features (peninsulas, for example).

The *so* version sets up the full smooth. The *sf* version sets up just the boundary interpolating soap film, while the *sw* version sets up the wiggly component of a soap film (zero on the boundary). The latter two are useful for forming tensor products with soap films, and can be used with [gamm](#) and [gamm4](#). To use these to simply set up a basis, then call via the wrapper [\*smooth.construct2\*](#) or [\*smoothCon\*](#).

## Usage

```
S3 method for class 'so.smooth.spec'
smooth.construct(object,data,knots)
S3 method for class 'sf.smooth.spec'
smooth.construct(object,data,knots)
S3 method for class 'sw.smooth.spec'
smooth.construct(object,data,knots)
```

## Arguments

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b> | A smooth specification object as produced by a <code>s(...,bs="so",xt=list(bnd=bnd,...))</code> term in a <code>gam</code> formula. Note that the <code>xt</code> argument to <code>s</code> *must* be supplied, and should be a list, containing at least a boundary specification list (see details). <code>xt</code> may also contain various options controlling the boundary smooth (see details), and PDE solution grid. The dimension of the bases for boundary loops is specified via the <code>k</code> argument of <code>s</code> , either as a single number to be used for each boundary loop, or as a vector of different basis dimensions for the various boundary loops. |
| <b>data</b>   | A list or data frame containing the arguments of the smooth.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>knots</b>  | list or data frame with two named columns specifying the knot locations within the boundary. The column names should match the names of the arguments of the smooth. The number of knots defines the *interior* basis dimension (i.e. it is *not* supplied via argument <code>k</code> of <code>s</code> ).                                                                                                                                                                                                                                                                                                                                                                             |

## Details

For soap film smooths the following \*must\* be supplied:

- `k` the basis dimension for each boundary loop smooth.
- `xt$bnd` the boundary specification for the smooth.
- `knots` the locations of the interior knots for the smooth.

When used in a GAM then `k` and `xt` are supplied via `s` while `knots` are supplied in the `knots` argument of [gam](#).

The `bnd` element of the `xt` list is a list of lists (or data frames), specifying the loops that define the boundary. Each boundary loop list must contain 2 columns giving the co-ordinates of points defining a boundary loop (when joined sequentially by line segments). Loops should not intersect (not checked). A point is deemed to be in the region of interest if it is interior to an odd number

of boundary loops. Each boundary loop list may also contain a column `f` giving known boundary conditions on a loop.

The `bndSpec` element of `xt`, if non-NULL, should contain

- `bs` the type of cyclic smoothing basis to use: one of "cc" and "cp". If not "cc" then a cyclic p-spline is used, and argument `m` must be supplied.
- `knot.space` set to "even" to get even knot spacing with the "cc" basis.
- `m` 1 or 2 element array specifying order of "cp" basis and penalty.

Currently the code will not deal with more than one level of nesting of loops, or with separate loops without an outer enclosing loop: if there are known boundary conditions (identifiability constraints) get awkward).

Note that the function `locator` provides a simple means for defining boundaries graphically, using something like `bnd <- as.data.frame(locator(type="l"))`, after producing a plot of the domain of interest (right click to stop). If the real boundary is very complicated, it is probably better to use a simpler smooth boundary enclosing the true boundary, which represents the major boundary features that you don't want to smooth across, but doesn't follow every tiny detail.

Model set up, and prediction, involves evaluating basis functions which are defined as the solution to PDEs. The PDEs are solved numerically on a grid using sparse matrix methods, with bilinear interpolation used to obtain values at any location within the smoothing domain. The dimension of the PDE solution grid can be controlled via element `nmax` (default 200) of the list supplied as argument `xt` of `s` in a `gam` formula: it gives the number of cells to use on the longest grid side.

A little theory: the soap film smooth  $f(x, y)$  is defined as the solution of

$$f_{xx} + f_{yy} = g$$

subject to the condition that  $f = s$ , on the boundary curve, where  $s$  is a smooth function (usually a cyclic penalized regression spline). The function  $g$  is defined as the solution of

$$g_{xx} + g_{yy} = 0$$

where  $g = 0$  on the boundary curve and  $g(x_k, y_k) = c_k$  at the 'knots' of the surface; the  $c_k$  are model coefficients.

In the simplest case, estimation of the coefficients of  $f$  (boundary coefficients plus  $c_k$ 's) is by minimization of

$$\|z - f\|^2 + \lambda_s J_s(s) + \lambda_f J_f(f)$$

where  $J_s$  is usually some cubic spline type wigginess penalty on the boundary smooth and  $J_f$  is the integral of  $(f_x x + f_y y)^2$  over the interior of the boundary. Both penalties can be expressed as quadratic forms in the model coefficients. The  $\lambda$ 's are smoothing parameters, selectable by GCV, REML, AIC, etc.  $z$  represents noisy observations of  $f$ .

### Value

A list with all the elements of object plus

|                   |                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>sd</code>   | A list defining the PDE solution grid and domain boundary, and including the sparse LU factorization of the PDE coefficient matrix. |
| <code>X</code>    | The model matrix: this will have an "offset" attribute, if there are any known boundary conditions.                                 |
| <code>S</code>    | List of smoothing penalty matrices (in smallest non-zero submatrix form).                                                           |
| <code>irng</code> | A vector of scaling factors that have been applied to the model matrix, to ensure nice conditioning.                                |

In addition there are all the elements usually added by `smooth.construct` methods.

## WARNINGS

Soap film smooths are quite specialized, and require more setup than most smoothers (e.g. you have to supply the boundary and the interior knots, plus the boundary smooth basis dimension(s)). It is worth looking at the reference.

smooth.construct.sos.smooth.spec  
*Splines on the sphere*

### Description

`gam` can use isotropic smooths on the sphere, via terms like `s(la,lo,bs="sos",m=2,k=100)`. There must be exactly 2 arguments to such a smooth. The first is taken to be latitude (in degrees) and the second longitude (in degrees). `m` (default 0) is an integer in the range -1 to 4 determining the order of the penalty used. For  $m > 0$ ,  $(m+2)/2$  is the penalty order, with  $m=2$  equivalent to the usual second derivative penalty.  $m=0$  signals to use the 2nd order spline on the sphere, computed by Wendelberger's (1981) method.  $m = -1$  results in a [Duchon.spline](#) being used (with  $m=2$  and  $s=1/2$ ), following an unpublished suggestion of Jean Duchon.

`k` (default 50) is the basis dimension.

### Usage

```

S3 method for class 'sos.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'sos.smooth'
Predict.matrix(object, data)

```

### Arguments

|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a smooth specification object, usually generated by a term <code>s(...,bs="sos",...)</code> .                                                                                                                 |
| <code>data</code>   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| <code>knots</code>  | a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code> .                                                                    |

### Details

For  $m > 0$ , the smooths implemented here are based on the pseudosplines on the sphere of Wahba (1981) (there is a correction of table 1 in 1982, but the correction has a misprint in the definition of  $A$  — the  $A$  given in the 1981 paper is correct). For  $m=0$  (default) then a second order spline on the sphere is used which is the analogue of a second order thin plate spline in 2D: the computation is based on Chapter 4 of Wendelberger, 1981. Optimal low rank approximations are obtained using exactly the approach given in Wood (2003). For  $m = -1$  a smooth of the general type discussed in Duchon (1977) is used: the sphere is embedded in a 3D Euclidean space, but smoothing employs a penalty based on second derivatives (so that locally as the smoothing parameter tends to zero we recover a "normal" thin plate spline on the tangent space). This is an unpublished suggestion of Jean Duchon.

Note that the null space of the penalty is always the space of constant functions on the sphere, whatever the order of penalty.

This class has a plot method, with 3 schemes. `scheme==0` plots one hemisphere of the sphere, projected onto a circle. The plotting sphere has the north pole at the top, and the 0 meridian running down the middle of the plot, and towards the viewer. The smoothing sphere is rotated within the plotting sphere, by specifying the location of its pole in the co-ordinates of the viewing sphere. `theta, phi` give the longitude and latitude of the smoothing sphere pole within the plotting sphere (in plotting sphere co-ordinates). (You can visualize the smoothing sphere as a globe, free to rotate within the fixed transparent plotting sphere.) The value of the smooth is shown by a heat map overlaid with a contour plot. `lat, lon` gridlines are also plotted.

`scheme==1` is as `scheme==0`, but in black and white, without the image plot. `scheme>1` calls the default plotting method with `scheme` decremented by 2.

### Value

An object of class "`sos.smooth`". In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

|                 |                                                                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>Xu</code> | A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations). |
| <code>UZ</code> | The matrix mapping the parameters of the reduced rank spline back to the parameters of a full spline.                                |

**smooth.construct.tensor.smooth.spec***Tensor product smoothing constructor***Description**

A special `smooth.construct` method function for creating tensor product smooths from any combination of single penalty marginal smooths.

**Usage**

```
S3 method for class 'tensor.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

|                     |                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a smooth specification object of class <code>tensor.smooth.spec</code> , usually generated by a term like <code>te(x, z)</code> in a <code>gam</code> model formula                                           |
| <code>data</code>   | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| <code>knots</code>  | a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code> . See details for further information.                               |

**Details**

Tensor product smooths are smooths of several variables which allow the degree of smoothing to be different with respect to different variables. They are useful as smooth interaction terms, as they are invariant to linear rescaling of the covariates, which means, for example, that they are insensitive to the measurement units of the different covariates. They are also useful whenever isotropic smoothing is inappropriate. See `te`, `smooth.construct` and `smooth.terms`.

**Value**

An object of class "tensor.smooth". See `smooth.construct`, for the elements that this object will contain.

**smooth.construct.tp.smooth.spec**

*Penalized thin plate regression splines in GAMs*

**Description**

`gam` can use isotropic smooths of any number of variables, specified via terms like `s(x, z, bs="tp", m=3)` (or just `s(x, z)` as this is the default basis). These terms are based on thin plate regression splines. `m` specifies the order of the derivatives in the thin plate spline penalty. If `m` is a vector of length 2 and the second element is zero, then the penalty null space of the smooth is not included in the smooth.

Thin plate regression splines are constructed by starting with the basis and penalty for a full thin plate spline and then truncating this basis in an optimal manner, to obtain a low rank smoother. Details are given in Wood (2003). One key advantage of the approach is that it avoids the knot placement problems of conventional regression spline modelling, but it also has the advantage that smooths of lower rank are nested within smooths of higher rank, so that it is legitimate to use conventional hypothesis testing methods to compare models based on pure regression splines. Note that the basis truncation does not change the meaning of the thin plate spline penalty (it penalizes exactly what it would have penalized for a full thin plate spline).

The t.p.r.s. basis and penalties can become expensive to calculate for large datasets. For this reason the default behaviour is to randomly subsample `max.knots` unique data locations if there are more than `max.knots` such, and to use the sub-sample for basis construction. The sampling is always done with the same random seed to ensure repeatability (does not reset R RNG). `max.knots` is 2000, by default. Both seed and `max.knots` can be modified using the `xt` argument to `s`. Alternatively the user can supply knots from which to construct a basis.

The "ts" smooths are t.p.r.s. with the penalty modified so that the term is shrunk to zero for high enough smoothing parameter, rather than being shrunk towards a function in the penalty null space (see details).

**Usage**

```
S3 method for class 'tp.smooth.spec'
smooth.construct(object, data, knots)
S3 method for class 'ts.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

`object` a smooth specification object, usually generated by a term `s(..., bs="tp", ...)` or `s(..., bs="ts", ...)`

|              |                                                                                                                                                                                                               |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>data</b>  | a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element. |
| <b>knots</b> | a list containing any knots supplied for basis setup — in same order and with same names as data. Can be NULL                                                                                                 |

## Details

The default basis dimension for this class is  $k=M+k\text{.def}$  where  $M$  is the null space dimension (dimension of unpenalized function space) and  $k\text{.def}$  is 8 for dimension 1, 27 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by its smoothing parameter).

The default is to set  $m$  (the order of derivative in the thin plate spline penalty) to the smallest value satisfying  $2m > d+1$  where  $d$  is the number of covariates of the term: this yields 'visually smooth' functions. In any case  $2m>d$  must be satisfied.

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

For these classes the specification `object` will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 3000 'knots' from which to produce a `tprs` basis, if the number of unique predictor variable combinations in excess of 3000. The default can be modified via the `xt` argument to `s`. This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 3000, and the random number seed to use (either can be missing).

For these bases `knots` has two uses. Firstly, as mentioned already, for large datasets the calculation of the `tp` basis can be time-consuming. The user can retain most of the advantages of the `t.p.r.s.` approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension,  $k$ . This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the `t.p.r.s.` basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension,  $k$ . For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

The shrinkage version of the `smooth`, eigen-decomposes the wigginess penalty matrix, and sets its zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

## Value

An object of class "tprs.smooth" or "ts.smooth". In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:

|              |                                                                                                                                                                                               |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>shift</b> | A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term. |
| <b>Xu</b>    | A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).                                                          |

|                      |                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------|
| UZ                   | The matrix mapping the t.p.r.s. parameters back to the parameters of a full thin plate spline.                     |
| null.space.dimension | The dimension of the space of functions that have zero wigginess according to the wigginess penalty for this term. |

smooth.terms

*Smooth terms in GAM*

## Description

Smooth terms are specified in a `gam` formula using `s`, `te` and `t2` terms. Various smooth classes are available, for different modelling tasks, and users can add smooth classes (see `user.defined.smooth`). What defines a smooth class is the basis used to represent the smooth function and quadratic penalty (or multiple penalties) used to penalize the basis coefficients in order to control the degree of smoothness. Smooth classes are invoked directly by `s` terms, or as building blocks for tensor product smoothing via `te` or `t2` terms (only smooth classes with single penalties can be used in tensor products). The smooths built into the `mgcv` package are all based one way or another on low rank versions of splines. For the full rank versions see Wahba (1990).

Note that smooths can be used rather flexibly in `gam` models. In particular the linear predictor of the GAM can depend on (a discrete approximation to) any linear functional of a smooth term, using by variables and the ‘summation convention’ explained in `linear.functional.terms`.

The single penalty built in smooth classes are summarized as follows

**Thin plate regression splines** `bs="tp"`. These are low rank isotropic smoothers of any number of covariates. By isotropic is meant that rotation of the covariate co-ordinate system will not change the result of smoothing. By low rank is meant that they have far fewer coefficients than there are data to smooth. They are reduced rank versions of the thin plate splines and use the thin plate spline penalty. They are the default smooth for `s` terms because there is a defined sense in which they are the optimal smoother of any given basis dimension/rank (Wood, 2003). Thin plate regression splines do not have ‘knots’ (at least not in any conventional sense): a truncated eigen-decomposition is used to achieve the rank reduction. See `tprs` for further details.

`bs="ts"` is as “`tp`” but with a modification to the smoothing penalty, so that the null space is also penalized slightly and the whole term can therefore be shrunk to zero.

**Duchon splines** `bs="ds"`. These generalize thin plate splines. In particular, for any given number of covariates they allow lower orders of derivative in the penalty than thin plate splines (and hence a smaller null space). See `Duchon.spline` for further details.

**Cubic regression splines** `bs="cr"`. These have a cubic spline basis defined by a modest sized set of knots spread evenly through the covariate values. They are penalized by the conventional intergrated square second derivative cubic spline penalty. For details see [cubic.regression.spline](#) and e.g. Wood (2006a).

`bs="cs"` specifies a shrinkage version of `"cr"`.

`bs="cc"` specifies a cyclic cubic regression splines (see [cyclic.cubic.spline](#)). i.e. a penalized cubic regression splines whose ends match, up to second derivative.

**Splines on the sphere** `bs="sos"`. These are two dimensional splines on a sphere. Arguments are latitude and longitude, and they are the analogue of thin plate splines for the sphere. Useful for data sampled over a large portion of the globe, when isotropy is appropriate. See [Spherical.Spline](#) for details.

**P-splines** `bs="ps"`. These are P-splines as proposed by Eilers and Marx (1996). They combine a B-spline basis, with a discrete penalty on the basis coefficients, and any sane combination of penalty and basis order is allowed. Although this penalty has no exact interpretation in terms of function shape, in the way that the derivative penalties do, P-splines perform almost as well as conventional splines in many standard applications, and can perform better in particular cases where it is advantageous to mix different orders of basis and penalty.

`bs="cp"` gives a cyclic version of a P-spline (see [cyclic.p.spline](#)).

**Random effects** `bs="re"`. These are parametric terms penalized by a ridge penalty (i.e. the identity matrix). When such a smooth has multiple arguments then it represents the parametric interaction of these arguments, with the coefficients penalized by a ridge penalty. The ridge penalty is equivalent to an assumption that the coefficients are i.i.d. normal random effects. See [smooth.construct.re.smooth.spec](#).

**Markov Random Fields** `bs="mrf"`. These are popular when space is split up into discrete contiguous geographic units (districts of a town, for example). In this case a simple smoothing penalty is constructed based on the neighbourhood structure of the geographic units. See [mrf](#) for details and an example.

**Soap film smooths** `bs="so"` (actually not single penaltied, but `bs="sw"` and `bs="sf"` allows splitting into single penalty components for use in tensor product smoothing). These are finite area smoothers designed to smooth within complicated geographical boundaries, where the boundary matters (e.g. you do not want to smooth across boundary features). See [soap](#) for details.

Broadly speaking the default penalized thin plate regression splines tend to give the best MSE performance, but they are slower to set up than the other bases. The knot based penalized cubic regression splines (with derivative based penalties) usually come next in MSE performance, with the P-splines doing just a little worse. However the P-splines are useful in non-standard situations.

All the preceding classes (and any user defined smooths with single penalties) may be used as marginal bases for tensor product smooths specified via `te` or `t2` terms. Tensor product smooths are smooth functions of several variables where the basis is built up from tensor products of bases for smooths of fewer (usually one) variable(s) (marginal bases). The multiple penalties for these smooths are produced automatically from the penalties of the marginal smooths. Wood (2006b) and Wood, Scheipl and Faraway (2012), give the general recipe for these constructions. The `te` construction results in fewer, more interpretable, penalties, while the `t2` construction is more natural if you are interested in functional ANOVA decompositions. `t2` works with the `gamm4` package.

Tensor product smooths often perform better than isotropic smooths when the covariates of a smooth are not naturally on the same scale, so that their relative scaling is arbitrary. For example, if smoothing with respect to time and distance, an isotropic smoother will give very different results if the units are cm and minutes compared to if the units are metres and seconds: a tensor product smooth will give the same answer in both cases (see `te` for an example of this). Note that `te` terms are knot

based, and the thin plate splines seem to offer no advantage over cubic or P-splines as marginal bases.

Some further specialist smoothers that are not suitable for use in tensor products are also available.

**Adaptive smoothers** `bs="ad"` Univariate and bivariate adaptive smooths are available (see [adaptive.smooth](#)). These are appropriate when the degree of smoothing should itself vary with the covariates to be smoothed, and the data contain sufficient information to be able to estimate the appropriate variation. Because this flexibility is achieved by splitting the penalty into several ‘basis penalties’ these terms are not suitable as components of tensor product smooths, and are not supported by `gamm`.

**Factor smooth interactions** `bs="fs"` Smooth factor interactions are often produced using by variables (see [gam.models](#)), but a special smoother class (see [factor.smooth.interaction](#)) is available for the case in which a smooth is required at each of a large number of factor levels (for example a smooth for each patient in a study), and each smooth should have the same smoothing parameter. The “`fs`” smoothers are set up to be efficient when used with `gamm`, and have penalties on each null sapce component (i.e. they are fully ‘random effects’).

smoothCon*Prediction/Construction wrapper functions for GAM smooth terms*

---

## Description

Wrapper functions for construction of and prediction from smooth terms in a GAM. The purpose of the wrappers is to allow user-transparent re-parameterization of smooth terms, in order to allow identifiability constraints to be absorbed into the parameterization of each term, if required. The routine also handles ‘by’ variables and construction of identifiability constraints automatically, although this behaviour can be over-ridden.

## Usage

```
smoothCon(object,data,knots,absorb.cons=FALSE,
 scale.penalty=TRUE,n=nrow(data),dataX=NULL,
 null.space.penalty=FALSE,sparse.cons=0)
PredictMat(object,data,n=nrow(data))
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object             | is a smooth specification object or a smooth object.                                                                                                                                                                                                                                                                                                                                            |
| data               | A data frame, model frame or list containing the values of the (named) covariates at which the smooth term is to be evaluated. If it’s a list then n must be supplied.                                                                                                                                                                                                                          |
| knots              | An optional data frame supplying any knot locations to be supplied for basis construction.                                                                                                                                                                                                                                                                                                      |
| absorb.cons        | Set to TRUE in order to have identifiability constraints absorbed into the basis.                                                                                                                                                                                                                                                                                                               |
| scale.penalty      | should the penalty coefficient matrix be scaled to have approximately the same ‘size’ as the inner product of the terms model matrix with itself? This can improve the performance of <a href="#">gamm</a> fitting.                                                                                                                                                                             |
| n                  | number of values for each covariate, or if a covariate is a matrix, the number of rows in that matrix: must be supplied explicitly if data is a list.                                                                                                                                                                                                                                           |
| dataX              | Sometimes the basis should be set up using data in data, but the model matrix should be constructed with another set of data provided in dataX — n is assumed to be the same for both. Facilitates smooth id’s.                                                                                                                                                                                 |
| null.space.penalty | Should an extra penalty be added to the smooth which will penalize the components of the smooth in the penalty null space: provides a way of penalizing terms out of the model altogether.                                                                                                                                                                                                      |
| sparse.cons        | If 0 then default sum to zero constraints are used. If -1 then sweep and drop sum to zero constraints are used (default with <a href="#">bam</a> ). If 1 then one coefficient is set to zero as constraint for sparse smooths. If 2 then sparse coefficient sum to zero constraints are used for sparse smooths. None of these options has an effect if the smooth supplies its own constraint. |

## Details

These wrapper functions exist to allow smooths specified using [smooth.construct](#) and [Predict.matrix](#) method functions to be re-parameterized so that identifiability constraints are no

longer required in fitting. This is done in a user transparent manner, but is typically of no importance in use of GAMs. The routine's also handle by variables and will create default identifiability constraints.

If a user defined smooth constructor handles by variables itself, then its returned smooth object should contain an object by .done. If this does not exist then smoothCon will use the default code. Similarly if a user defined Predict.matrix method handles by variables internally then the returned matrix should have a "by.done" attribute.

Default centering constraints, that terms should sum to zero over the covariates, are produced unless the smooth constructor includes a matrix C of constraints. To have no constraints (in which case you had better have a full rank penalty!) the matrix C should have no rows. There is an option to use centering constraint that generate no, or limited infl, if the smoother has a sparse model matrix. smoothCon returns a list of smooths because factor by variables result in multiple copies of a smooth, each multiplied by the dummy variable associated with one factor level. smoothCon modifies the smooth object labels in the presence of by variables, to ensure that they are unique, it also stores the level of a by variable factor associated with a smooth, for later use by PredictMat.

The parameterization used by `gam` can be controlled via `gam.control`.

## Value

From smoothCon a list of smooth objects returned by the appropriate `smooth.construct` method function. If constraints are to be absorbed then the objects will have attributes "qrc" and "nCons". "nCons" is the number of constraints. "qrc" is usually the qr decomposition of the constraint matrix (returned by `qr`), but if it is a single positive integer it is the index of the coefficient to set to zero, and if it is a negative number then this indicates that the parameters are to sum to zero.

For predictMat a matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in object.

sp.vcov

*Extract smoothing parameter estimator covariance matrix from (RE)ML GAM fit*

---

## Description

Extracts the estimated covariance matrix for the log smoothing parameter estimates from a (RE)ML estimated `gam` object, provided the fit was with a method that evaluated the required Hessian.

## Usage

`sp.vcov(x)`

### Arguments

- x a fitted model object of class `gam` as produced by `gam()`.

### Details

Just extracts the inverse of the hessian matrix of the negative (restricted) log likelihood w.r.t the log smoothing parameters, if this has been obtained as part of fitting.

### Value

A matrix corresponding to the estimated covariance matrix of the log smoothing parameter estimators, if this can be extracted, otherwise NULL. If the scale parameter has been (RE)ML estimated (i.e. if the method was "ML" or "REML" and the scale parameter was unknown) then the last row and column relate to the log scale parameter.

### Examples

```
require(mgcv)
n <- 100
x <- runif(n);z <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=10)+s(z),knots=list(x=seq(0,1,length=10)),
 method="REML")
sp.vcov(mod)
```

### Description

These are experimental sparse smoothing functions, and should be left well alone!

### Usage

```
spasm.construct(object,data)
spasm.sp(object,sp,w=rep(1,object$nobs),get.trH=TRUE,block=0,centre=FALSE)
spasm.smooth(object,X,residual=FALSE,block=0)
```

### Arguments

|          |                                                                |
|----------|----------------------------------------------------------------|
| object   | sparse smooth object                                           |
| data     | data frame                                                     |
| sp       | smoothing parameter value                                      |
| w        | optional weights                                               |
| get.trH  | Should (estimated) trace of sparse smoother matrix be returned |
| block    | index of block, 0 for all blocks                               |
| centre   | should sparse smooth be centred?                               |
| X        | what to smooth                                                 |
| residual | apply residual operation?                                      |

step.gam

*Alternatives to step.gam*

### Description

There is no `step.gam` in package `mgcv`. The `mgcv` default for model selection is to use either prediction error criteria such as GCV, GACV, Mallows' Cp/AIC/UBRE or the likelihood based methods of REML or ML. Since the smoothness estimation part of model selection is done in this way it is logically most consistent to perform the rest of model selection in the same way. i.e. to decide which terms to include or omit by looking at changes in GCV, AIC, REML etc.

To facilitate fully automatic model selection the package implements two smooth modification techniques which can be used to allow smooths to be shrunk to zero as part of smoothness selection.

**Shrinkage smoothers** are smoothers in which a small multiple of the identity matrix is added to the smoothing penalty, so that strong enough penalization will shrink all the coefficients of the smooth to zero. Such smoothers can effectively be penalized out of the model altogether, as part of smoothing parameter estimation. 2 classes of these shrinkage smoothers are implemented: "cs" and "ts", based on cubic regression spline and thin plate regression spline smoothers (see `s`)

**Null space penalization** An alternative is to construct an extra penalty for each smooth which penalizes the space of functions of zero wigginess according to its existing penalties. If all the smoothing parameters for such a term tend to infinity then the term is penalized to zero, and is effectively dropped from the model. The advantage of this approach is that it can be implemented automatically for any smooth. The `select` argument to `gam` causes this latter approach to be used.

REML and ML smoothness selection are equivalent under this approach, and simulation evidence suggests that they tend to perform a little better than prediction error criteria, for model selection.

**Examples**

```
an example of GCV based model selection as
an alternative to stepwise selection, using
shrinkage smoothers...
library(mgcv)
set.seed(0);n <- 400
dat <- gamSim(1,n=n,scale=2)
dat$x4 <- runif(n, 0, 1)
dat$x5 <- runif(n, 0, 1)
attach(dat)
Note the increased gamma parameter below to favour
slightly smoother models...
b<-gam(y~s(x0,bs="ts") + s(x1,bs="ts") + s(x2,bs="ts") +
 s(x3,bs="ts") + s(x4,bs="ts") + s(x5,bs="ts"),gamma=1.4)
summary(b)
plot(b, pages=1)

Same again using REML/ML
b<-gam(y~s(x0,bs="ts") + s(x1,bs="ts") + s(x2,bs="ts") +
 s(x3,bs="ts") + s(x4,bs="ts") + s(x5,bs="ts"),method="REML")
summary(b)
plot(b, pages=1)

And once more, but using the null space penalization
b<-gam(y~s(x0,bs="cr") + s(x1,bs="cr") + s(x2,bs="cr") +
 s(x3,bs="cr") + s(x4,bs="cr") + s(x5,bs="cr"),
 method="REML",select=TRUE)
summary(b)
plot(b, pages=1)

detach(dat);rm(dat)
```

**Description**

Takes a fitted `gam` object produced by `gam()` and produces various useful summaries from it. (See `sink` to divert output to a file.)

## Usage

```
S3 method for class 'gam'
summary(object, dispersion=NULL, freq=FALSE, p.type = 0, ...)

S3 method for class 'summary.gam'
print(x,digits = max(3, getOption("digits") - 3),
 signif.stars = getOption("show.signif.stars"),...)
```

## Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object       | a fitted <code>gam</code> object as produced by <code>gam()</code> .                                                                                                                                                                                                                                                                                                                                                        |
| x            | a <code>summary.gam</code> object produced by <code>summary.gam()</code> .                                                                                                                                                                                                                                                                                                                                                  |
| dispersion   | A known dispersion parameter. <code>NULL</code> to use estimate or default (e.g. 1 for Poisson).                                                                                                                                                                                                                                                                                                                            |
| freq         | By default p-values for parametric terms are calculated using the Bayesian estimated covariance matrix of the parameter estimators. If this is set to <code>TRUE</code> then the frequentist covariance matrix of the parameters is used instead.                                                                                                                                                                           |
| p.type       | determines how p-values are computed for smooth terms. 0 uses a test statistic with distribution determined by the un-rounded edf of the term. 1 uses upwardly biased rounding of the edf and -1 uses a version of the test statistic with a null distribution that has to be simulated. 5 is the approximation in Wood (2006). Other options are poor, generate a warning, and are only of research interest. See details. |
| digits       | controls number of digits printed in output.                                                                                                                                                                                                                                                                                                                                                                                |
| signif.stars | Should significance stars be printed alongside output.                                                                                                                                                                                                                                                                                                                                                                      |
| ...          | other arguments.                                                                                                                                                                                                                                                                                                                                                                                                            |

## Details

Model degrees of freedom are taken as the trace of the influence (or hat) matrix  $\mathbf{A}$  for the model fit. Residual degrees of freedom are taken as number of data minus model degrees of freedom. Let  $\mathbf{P}_i$  be the matrix giving the parameters of the  $i$ th smooth when applied to the data (or pseudodata in the generalized case) and let  $\mathbf{X}$  be the design matrix of the model. Then  $tr(\mathbf{XP}_i)$  is the edf for the  $i$ th term. Clearly this definition causes the edf's to add up properly! An alternative version of EDF is more appropriate for p-value computation, and is based on the trace of  $2\mathbf{A} - \mathbf{AA}$ .

`print.summary.gam` tries to print various bits of summary information useful for term selection in a pretty way.

Unless `p.type=5`, p-values for smooth terms are usually based on a test statistic motivated by an extension of Nychka's (1988) analysis of the frequentist properties of Bayesian confidence intervals for smooths. These have better frequentist performance (in terms of power and distribution under the null) than the alternative strictly frequentist approximation. When the Bayesian intervals have good across the function properties then the p-values have close to the correct null distribution and reasonable power (but there are no optimality results for the power).

Let  $\mathbf{f}$  denote the vector of values of a smooth term evaluated at the original covariate values and let  $\mathbf{V}_f$  denote the corresponding Bayesian covariance matrix. Let  $\mathbf{V}_f^{r-}$  denote the rank  $r$  pseudoinverse of  $\mathbf{V}_f$ , where  $r$  is the EDF for the term. The statistic used is then

$$T = \mathbf{f}^T \mathbf{V}_f^{r-} \mathbf{f}$$

(this can be calculated efficiently without forming the pseudoinverse explicitly).  $T$  is compared to an approximation to an appropriate weighted sum of chi-squared random variables.

The non-integer rank truncated inverse is constructed to give an approximation varying smoothly between the bounding integer rank approximations, while yielding test statistics with the correct mean and variance under the null. Alternatively (`p.type==1`)  $r$  is obtained by biased rounding of the EDF: values less than .05 above the preceding integer are rounded down, while other values are rounded up. Another option (`p.type==1`) uses a statistic of formal rank given by the number of coefficients for the smooth, but with its terms weighted by the eigenvalues of the covariance matrix, so that penalized terms are down-weighted, but the null distribution requires simulation. Other options for `p.type` are 2 (naive rounding), 3 (round up), 4 (numerical rank determination): these are poor options for theoretically known reasons, and will generate a warning.

The default p-values also have a Bayesian interpretation: the probability of observing an  $f$  less probable than 0, under the approximation for the posterior for  $f$  implied by the truncation used in the test statistic.

Note that for terms with no unpenalized terms the Nychka (1988) requirement for smoothing bias to be substantially less than variance breaks down (see e.g. appendix of Marra and Wood, 2012), and this results in incorrect null distribution for p-values computed using the above approach. In this case it is necessary to use an alternative approach designed for random effects variance components.

In this zero-dimensional null space/random effects case, the p-values are again conditional on the smoothing parameters/variance component estimates, and may therefore be somewhat too low when these are subject to large uncertainty. The idea is to condition on the smoothing parameter estimates, and then to use the likelihood ratio test statistic conditional on those estimates. The distribution of this test statistic under the null is computable as a weighted sum of chi-squared random variables.

In simulations the p-values have best behaviour under ML smoothness selection, with REML coming second. In general the p-values behave well, but conditioning on the smoothing parameters means that they may be somewhat too low when smoothing parameters are highly uncertain. High uncertainty happens in particular when smoothing parameters are poorly identified, which can occur with nested smooths or highly correlated covariates (high concurvity).

If `p.type=5` then the frequentist approximation for p-values of smooth terms described in section 4.8.5 of Wood (2006) is used. The approximation is not great. If  $\mathbf{p}_i$  is the parameter vector for the  $i$ th smooth term, and this term has estimated covariance matrix  $\mathbf{V}_i$  then the statistic is  $\mathbf{p}'_i \mathbf{V}_i^{k-} \mathbf{p}_i$ , where  $\mathbf{V}_i^{k-}$  is the rank  $k$  pseudo-inverse of  $\mathbf{V}_i$ , and  $k$  is estimated rank of  $\mathbf{V}_i$ . p-values are obtained as follows. In the case of known dispersion parameter, they are obtained by comparing the `chi.sq` statistic to the chi-squared distribution with  $k$  degrees of freedom, where  $k$  is the estimated rank of  $\mathbf{V}_i$ . If the dispersion parameter is unknown (in which case it will have been estimated) the statistic is compared to an F distribution with  $k$  upper d.f. and lower d.f. given by the residual degrees of freedom for the model. Typically the p-values will be somewhat too low.

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (`freq=TRUE`), since the parametric terms themselves are usually unpenalized. Default P-values for parameteric terms that are penalized using the `paraPen` argument will not be good. However if such terms represent conventional random effects with full rank penalties, then setting `freq=TRUE` is appropriate.

## Value

`summary.gam` produces a list of summary information for a fitted `gam` object.

- |                      |                                                                              |
|----------------------|------------------------------------------------------------------------------|
| <code>p.coeff</code> | is an array of estimates of the strictly parametric model coefficients.      |
| <code>p.t</code>     | is an array of the <code>p.coeff</code> 's divided by their standard errors. |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| p.pv          | is an array of p-values for the null hypothesis that the corresponding parameter is zero. Calculated with reference to the t distribution with the estimated residual degrees of freedom for the model fit if the dispersion parameter has been estimated, and the standard normal if not.                                                                                                                                                                                                             |
| m             | The number of smooth terms in the model.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| chi.sq        | An array of test statistics for assessing the significance of model smooth terms. See details.                                                                                                                                                                                                                                                                                                                                                                                                         |
| s.pv          | An array of approximate p-values for the null hypotheses that each smooth term is zero. Be warned, these are only approximate.                                                                                                                                                                                                                                                                                                                                                                         |
| se            | array of standard error estimates for all parameter estimates.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| r.sq          | The adjusted r-squared for the model. Defined as the proportion of variance explained, where original variance and residual variance are both estimated using unbiased estimators. This quantity can be negative if your model is worse than a one parameter constant model, and can be higher for the smaller of two nested models! The proportion null deviance explained is probably more appropriate for non-normal errors. Note that r.sq does not include any offset in the one parameter model. |
| dev.expl      | The proportion of the null deviance explained by the model. The null deviance is computed taking account of any offset, so dev.expl can be substantially lower than r.sq when an offset is present.                                                                                                                                                                                                                                                                                                    |
| edf           | array of estimated degrees of freedom for the model terms.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| residual.df   | estimated residual degrees of freedom.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| n             | number of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| method        | The smoothing selection criterion used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| sp.criterion  | The minimized value of the smoothness selection criterion. Note that for ML and REML methods, what is reported is the negative log marginal likelihood or negative log restricted likelihood.                                                                                                                                                                                                                                                                                                          |
| scale         | estimated (or given) scale parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| family        | the family used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| formula       | the original GAM formula.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| dispersion    | the scale parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| pTerms.df     | the degrees of freedom associated with each parametric term (excluding the constant).                                                                                                                                                                                                                                                                                                                                                                                                                  |
| pTerms.chi.sq | a Wald statistic for testing the null hypothesis that the each parametric term is zero.                                                                                                                                                                                                                                                                                                                                                                                                                |
| pTerms.pv     | p-values associated with the tests that each term is zero. For penalized fits these are approximate. The reference distribution is an appropriate chi-squared when the scale parameter is known, and is based on an F when it is not.                                                                                                                                                                                                                                                                  |
| cov.unscaled  | The estimated covariance matrix of the parameters (or estimators if freq=TRUE), divided by scale parameter.                                                                                                                                                                                                                                                                                                                                                                                            |
| cov.scaled    | The estimated covariance matrix of the parameters (estimators if freq=TRUE).                                                                                                                                                                                                                                                                                                                                                                                                                           |
| p.table       | significance table for parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| s.table       | significance table for smooths                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| p.Terms       | significance table for parametric model terms                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## WARNING

The p-values are approximate and conditional on the smoothing parameters, they are likely to be somewhat too low when smoothing parameter estimates are highly uncertain: do read the details section.

P-values for terms penalized via ‘paraPen’ are unlikely to be correct.

## Examples

```
library(mgcv)
set.seed(0)
dat <- gamSim(1,n=200,scale=2) ## simulate data

b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat)
plot(b,pages=1)
summary(b)

now check the p-values by using a pure regression spline.....
b.d <- round(summary(b)$edf)+1 ## get edf per smooth
b.d <- pmax(b.d,3) # can't have basis dimension less than 3!
bc<-gam(y~s(x0,k=b.d[1],fx=TRUE)+s(x1,k=b.d[2],fx=TRUE)+
 s(x2,k=b.d[3],fx=TRUE)+s(x3,k=b.d[4],fx=TRUE),data=dat)
plot(bc,pages=1)
summary(bc)

Example where some p-values are less reliable...
dat <- gamSim(6,n=200,scale=2)
b <- gam(y~s(x0,m=1)+s(x1)+s(x2)+s(x3)+s(fac,bs="re"),data=dat)
Here s(x0,m=1) can be penalized to zero, so p-value approximation
cruder than usual...
summary(b)
Now force summary to report approximate p-value for "re"
terms as well. In this case the p-value is OK, since the
random effect structure is so simple.
summary(b,all.p=TRUE)
```

```

p-value check - increase k to make this useful!
k<-20;n <- 200;p <- rep(NA,k)
for (i in 1:k)
{ b<-gam(y~te(x,z),data=data.frame(y=rnorm(n),x=runif(n),z=runif(n)),
 method="ML")
 p[i]<-summary(b)$s.p[1]
}
plot(((1:k)-0.5)/k,sort(p))
abline(0,1,col=2)
ks.test(p,"punif") ## how close to uniform are the p-values?

```

t2

*Define alternative tensor product smooths in GAM formulae*

## Description

Alternative to [te](#) for defining tensor product smooths in a [gam](#) formula. Results in a construction in which the penalties are non-overlapping multiples of identity matrices (with some rows and columns zeroed). The construction, which is due to Fabian Scheipl, is analogous to Smoothing Spline ANOVA (Gu, 2002), but using low rank penalized regression spline marginals. The main advantage of this construction is that it is useable with [gamm4](#) from package [gamm4](#).

## Usage

```
t2(..., k=NA,bs="cr",m=NA,d=NA,by=NA,xt=NULL,
 id=NULL,sp=NULL,full=FALSE,ord=NULL)
```

## Arguments

|     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ... | a list of variables that are the covariates that this smooth is a function of.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| k   | the dimension(s) of the bases used to represent the smooth term. If not supplied then set to $5^d$ . If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See <a href="#">choose.k</a> for further information.                                                                                                                                                                |
| bs  | array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See <a href="#">smooth.terms</a> for details and full list. User defined bases can also be used here (see <a href="#">smooth.construct</a> for an example). If only one basis code is given then this is used for all bases. |
| m   | The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different m for each margin. For marginals that take vector m (e.g. <a href="#">p.spline</a> and <a href="#">Duchon.spline</a> ), then a list can be supplied, with a vector element for each margin. NA autoinitializes. m is ignored by some bases (e.g. "cr").                                                                          |

|      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d    | array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set d=c(2, 1). Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.                                                                                                                                                                                                                                                             |
| by   | a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). In the factor case causes a replicate of the smooth to be produced for each factor level. See <a href="#">gam.models</a> for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see <a href="#">gam.models</a> and <a href="#">linear.functional.terms</a> for details). |
| xt   | Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.                                                                                                                                                                                                                                                                                                                                                                                                          |
| id   | A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id then they will have the same smoothing paramsters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).                                                                                                                                                                                                                                 |
| sp   | any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to <a href="#">gam</a> . Ignored by <a href="#">gamm</a> .                                                                                                                                                                                                                    |
| full | If TRUE then there is a separate penalty for each combination of null space column and range space. This gives strict invariance. If FALSE each combination of null space and range space generates one penalty, but the coulmns of each null space basis are treated as one group. The latter is more parsimonious, but does mean that invariance is only achieved by an arbitrary rescaling of null space basis vectors.                                                                                                                                                |
| ord  | an array giving the orders of terms to retain. Here order means number of marginal range spaces used in the construction of the component. NULL to retain everything.                                                                                                                                                                                                                                                                                                                                                                                                     |

## Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices. These are reparameterized so that the penalty is zero everywhere, except for some elements on the leading diagonal, which all have the same non-zero value. This reparameterization results in an unpenalized and a penalized subset of parameters, for each marginal basis (see e.g. appendix of Wood, 2004, for details).

The re-parameterized marginal bases are then combined to produce a basis for a single function of all the covariates (dimension given by the product of the dimensions of the marginal bases). In this set up there are multiple penalty matrices — all zero, but for a mixture of a constant and zeros on the leading diagonal. No two penalties have a non-zero entry in the same place.

Essentially the basis for the tensor product can be thought of as being constructed from a set of products of the penalized (range) or unpenalized (null) space bases of the marginal smooths (see Gu, 2002, section 2.4). To construct one of the set, choose either the null space or the range space from each marginal, and from these bases construct a product basis. The result is subject to a ridge penalty (unless it happens to be a product entirely of marginal null spaces). The whole basis for

the smooth is constructed from all the different product bases that can be constructed in this way. The separately penalized components of the smooth basis each have an interpretation in terms of the ANOVA - decomposition of the term. See [pen.edf](#) for some further information.

Note that there are two ways to construct the product. When `full=FALSE` then the null space bases are treated as a whole in each product, but when `full=TRUE` each null space column is treated as a separate null space. The latter results in more penalties, but is the strict analog of the SS-ANOVA approach.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

Note also that GAMs constructed from lower rank tensor product smooths are nested within GAMs constructed from higher rank tensor product smooths if the same marginal bases are used in both cases (the marginal smooths themselves are just special cases of tensor product smooths.)

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

## Value

A class `t2.smooth.spec` object defining a tensor product smooth to be turned into a basis and penalties by the `smooth.construct.tensor.smooth.spec` function.

The returned object contains the following items:

|                     |                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>margin</code> | A list of <code>smooth.spec</code> objects of the type returned by <a href="#">s</a> , defining the basis from which the tensor product smooth is constructed.    |
| <code>term</code>   | An array of text strings giving the names of the covariates that the term is a function of.                                                                       |
| <code>by</code>     | is the name of any by variable as text ("NA" for none).                                                                                                           |
| <code>fx</code>     | logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise. |
| <code>label</code>  | A suitable text label for this smooth term.                                                                                                                       |
| <code>dim</code>    | The dimension of the smoother - i.e. the number of covariates that it is a function of.                                                                           |
| <code>mp</code>     | TRUE if multiple penalties are to be used (default).                                                                                                              |
| <code>np</code>     | TRUE to re-parameterize 1-D marginal smooths in terms of function values (default).                                                                               |
| <code>id</code>     | the <code>id</code> argument supplied to <code>te</code> .                                                                                                        |
| <code>sp</code>     | the <code>sp</code> argument supplied to <code>te</code> .                                                                                                        |

te

*Define tensor product smooths in GAM formulae*

## Description

Function used in definition of tensor product smooth terms within `gam` model formulae. The function does not evaluate a smooth - it exists purely to help set up a model using tensor product based smooths. Designed to construct tensor products from any marginal smooths with a basis-penalty representation (with the restriction that each marginal smooth must have only one penalty).

## Usage

```
te(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
 mp=TRUE, np=TRUE, xt=NULL, id=NULL, sp=NULL)
```

## Arguments

- ... a list of variables that are the covariates that this smooth is a function of.
- k the dimension(s) of the bases used to represent the smooth term. If not supplied then set to  $5^d$ . If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See [choose.k](#) for further information.
- bs array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See [smooth.terms](#) for details and full list. User defined bases can also be used here (see [smooth.construct](#) for an example). If only one basis code is given then this is used for all bases.

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>m</b>  | The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different <b>m</b> for each margin. For marginals that take vector <b>m</b> (e.g. <a href="#">p.spline</a> and <a href="#">Duchon.spline</a> ), then a list can be supplied, with a vector element for each margin. NA autoinitializes. <b>m</b> is ignored by some bases (e.g. "cr").                                                                                              |
| <b>d</b>  | array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set <b>d=c(2, 1)</b> . Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.                                                                                                                                                                                                                                                     |
| <b>by</b> | a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). In the factor case causes a replicate of the smooth to be produced for each factor level. See <a href="#">gam.models</a> for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see <a href="#">gam.models</a> and <a href="#">linear.functional.terms</a> for details). |
| <b>fx</b> | indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>mp</b> | TRUE to use multiple penalties for the smooth. FALSE to use only a single penalty: single penalties are not recommended - they tend to allow only rather wiggly models.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>np</b> | TRUE to use the ‘normal parameterization’ for a tensor product smooth. This represents any 1-d marginal smooths via parameters that are function values at ‘knots’, spread evenly through the data. The parameterization makes the penalties easily interpretable, however it can reduce numerical stability in some cases.                                                                                                                                                                                                                                               |
| <b>xt</b> | Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>id</b> | A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same <b>id</b> then they will have the same smoothing paramsters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).                                                                                                                                                                                                                          |
| <b>sp</b> | any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in <b>sp</b> argument to <a href="#">gam</a> . Ignored by <a href="#">gamm</a> .                                                                                                                                                                                                             |

## Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices, and these are then combined in the manner described in [tensor.prod.model.matrix](#) and [tensor.prod.penalties](#), to produce a single model matrix for the smooth, but multiple penalties (one for each marginal basis). The basis dimension of the whole smooth is the product of the basis dimensions of the marginal smooths.

An option for operating with a single penalty (The Kronecker product of the marginal penalties) is provided, but it is rarely of practical use: the penalty is typically so rank deficient that even the smoothest resulting model will have rather high estimated degrees of freedom.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

Note also that GAMs constructed from lower rank tensor product smooths are nested within GAMs constructed from higher rank tensor product smooths if the same marginal bases are used in both cases (the marginal smooths themselves are just special cases of tensor product smooths.)

The ‘normal parameterization’ (np=TRUE) re-parameterizes the marginal smooths of a tensor product smooth so that the parameters are function values at a set of points spread evenly through the range of values of the covariate of the smooth. This means that the penalty of the tensor product associated with any particular covariate direction can be interpreted as the penalty of the appropriate marginal smooth applied in that direction and averaged over the smooth. Currently this is only done for marginals of a single variable. This parameterization can reduce numerical stability when used with marginal smooths other than “cc”, “cr” and “cs”: if this causes problems, set np=FALSE.

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

### Value

A class `tensor.smooth.spec` object defining a tensor product smooth to be turned into a basis and penalties by the `smooth.construct.tensor.smooth.spec` function.

The returned object contains the following items:

|                     |                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>margin</code> | A list of <code>smooth.spec</code> objects of the type returned by <code>s</code> , defining the basis from which the tensor product smooth is constructed.       |
| <code>term</code>   | An array of text strings giving the names of the covariates that the term is a function of.                                                                       |
| <code>by</code>     | is the name of any by variable as text (“NA” for none).                                                                                                           |
| <code>fx</code>     | logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise. |
| <code>label</code>  | A suitable text label for this smooth term.                                                                                                                       |
| <code>dim</code>    | The dimension of the smoother - i.e. the number of covariates that it is a function of.                                                                           |
| <code>mp</code>     | TRUE if multiple penalties are to be used (default).                                                                                                              |
| <code>np</code>     | TRUE to re-parameterize 1-D marginal smooths in terms of function values (default).                                                                               |
| <code>id</code>     | the <code>id</code> argument supplied to <code>te</code> .                                                                                                        |
| <code>sp</code>     | the <code>sp</code> argument supplied to <code>te</code> .                                                                                                        |

## Description

Produce model matrices or penalty matrices for a tensor product smooth from the model matrices or penalty matrices for the marginal bases of the smooth.

## Usage

```
tensor.prod.model.matrix(X)
tensor.prod.penalties(S)
```

## Arguments

- |                |                                                             |
|----------------|-------------------------------------------------------------|
| <code>X</code> | a list of model matrices for the marginal bases of a smooth |
| <code>S</code> | a list of penalties for the marginal bases of a smooth.     |

## Details

If  $X[[1]], X[[2]] \dots X[[m]]$  are the model matrices of the marginal bases of a tensor product smooth then the  $i$ th row of the model matrix for the whole tensor product smooth is given by  $X[[1]][i,] \%x\% X[[2]][i,] \%x\% \dots X[[m]][i,]$ , where  $\%x\%$  is the Kronecker product. Of course the routine operates column-wise, not row-wise!

If  $S[[1]], S[[2]] \dots S[[m]]$  are the penalty matrices for the marginal bases, and  $I[[1]], I[[2]] \dots I[[m]]$  are corresponding identity matrices, each of the same dimension as its corresponding penalty, then the tensor product smooth has  $m$  associate penalties of the form:

$$\begin{aligned} & S[[1]] \%x\% I[[2]] \%x\% \dots I[[m]], \\ & I[[1]] \%x\% S[[2]] \%x\% \dots I[[m]] \\ & \dots \\ & I[[1]] \%x\% I[[2]] \%x\% \dots S[[m]]. \end{aligned}$$

Of course it's important that the model matrices and penalty matrices are presented in the same order when constructing tensor product smooths.

## Value

Either a single model matrix for a tensor product smooth, or a list of penalty terms for a tensor product smooth.

## Author(s)

S<-list(matrix(c(2,1,1,2),2,2),matrix(c(2,1,0,1,2,1,0,1,2),3,3))
tensor.prod.penalties(S)
```

Tweedie

*GAM Tweedie family*

## Description

A Tweedie family, designed for use with `gam` from the `mgcv` library. Restricted to variance function powers between 1 and 2. A useful alternative to `quasi` when a full likelihood is desirable.

## Usage

```
Tweedie(p=1, link = power(0))
```

## Arguments

- |                   |                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>p</code>    | the variance of an observation is proportional to its mean to the power <code>p</code> . <code>p</code> must be greater than 1 and less than or equal to 2. 1 would be Poisson, 2 is gamma. |
| <code>link</code> | The link function: one of "log", "identity", "inverse", "sqrt", or a <code>power</code> link.                                                                                               |

## Details

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution. The  $p=1$  case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For  $1 < p < 2$  the distribution is supported on the positive reals with a point mass at zero.  $p=2$  is a gamma distribution. As  $p$  gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at  $p=1$ , and is therefore highly multimodal. See `1dTweedie` for more on this behaviour.

`Tweedie` is based partly on the `poisson` family, and partly on `tweedie` from the `statmod` package. It includes extra components to work with all `mgcv` GAM fitting methods as well as an `aic` function. The required log density evaluation (+ derivatives w.r.t. scale) is based on the series evaluation method of Dunn and Smyth (2005).

Without the restriction on  $p$  the calculation of Tweedie densities is less straightforward, and there does not currently seem to be an implementation which offers any benefit over `quasi`. If you really need to this case then the `tweedie` package is the place to start.

## Value

An object inheriting from class `family`, with additional elements

- |                    |                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>dvar</code>  | the function giving the first derivative of the variance function w.r.t. <code>mu</code> .                                           |
| <code>d2var</code> | the function giving the second derivative of the variance function w.r.t. <code>mu</code> .                                          |
| <code>ls</code>    | A function returning a 3 element array: the saturated log likelihood followed by its first 2 derivatives w.r.t. the scale parameter. |

uniquecombs

*find the unique rows in a matrix*

**Description**

This routine returns a matrix containing all the unique rows of the matrix supplied as its argument. That is, all the duplicate rows are stripped out. Note that the ordering of the rows on exit is not the same as on entry. It also returns an index attribute for relating the result back to the original matrix.

**Usage**

`uniquecombs(x)`

## Arguments

`x` is an R matrix (numeric)

## Details

Models with more parameters than unique combinations of covariates are not identifiable. This routine provides a means of evaluating the number of unique combinations of coavariates in a model. The routine calls compiled C code.

## Value

A matrix consisting of the unique rows of `x` (in arbitrary order).

The matrix has an "index" attribute. `index[i]` gives the row of the returned matrix that contains row `i` of the original matrix.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

## See Also

[unique](#) can do the same thing, including for non-numeric matrices, but more slowly and without returning the index.

## Examples

```
require(mgcv)
X<-matrix(c(1,2,3,1,2,3,4,5,6,1,3,2,4,5,6,1,1,1),6,3,byrow=TRUE)
print(X)
Xu <- uniquecombs(X); Xu
ind <- attr(Xu,"index")
find the value for row 3 of the original from Xu
Xu[ind[3],]; X[3,]
```

## Description

Extracts the Bayesian posterior covariance matrix of the parameters or frequentist covariance matrix of the parameter estimators from a fitted `gam` object.

## Usage

```
S3 method for class 'gam'
vcov(object, freq = FALSE, dispersion = NULL, ...)
```

### Arguments

|            |                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| object     | fitted model object of class <code>gam</code> as produced by <code>gam()</code> .                                                                         |
| freq       | TRUE to return the frequentist covariance matrix of the parameter estimators, FALSE to return the Bayesian posterior covariance matrix of the parameters. |
| dispersion | a value for the dispersion parameter: not normally used.                                                                                                  |
| ...        | other arguments, currently ignored.                                                                                                                       |

### Details

Basically, just extracts `object$Ve` or `object$Vp` from a [gamObject](#).

### Value

A matrix corresponding to the estimated frequentist covariance matrix of the model parameter estimators/coefficients, or the estimated posterior covariance matrix of the parameters, depending on the argument `freq`.

### Author(s)

### Examples

```
require(mgcv)
n <- 100
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=10),knots=list(x=seq(0,1,length=10)))
diag(vcov(mod))
```

**vis.gam**

*Visualization of GAM objects*

### Description

Produces perspective or contour plot views of `gam` model predictions, fixing all but the values in `view` to the values supplied in `cond`.

### Usage

```
vis.gam(x,view=NULL,cond=list(),n.grid=30,too.far=0,col=NA,
 color="heat",contour.col=NULL,se=-1,type="link",
 plot.type="persp",zlim=NULL,nCol=50,...)
```

### Arguments

|             |                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x           | a <code>gam</code> object, produced by <code>gam()</code>                                                                                                                                                                                                                                                                                                                                   |
| view        | an array containing the names of the two main effect terms to be displayed on the x and y dimensions of the plot. If omitted the first two suitable terms will be used. Note that variables coerced to factors in the model formula won't work as view variables, and <code>vis.gam</code> can not detect that this has happened when setting defaults.                                     |
| cond        | a named list of the values to use for the other predictor terms (not in <code>view</code> ). Variables omitted from this list will have the closest observed value to the median for continuous variables, or the most commonly occurring level for factors. Parametric matrix variables have all the entries in each column set to the observed column entry closest to the column median. |
| n.grid      | The number of grid nodes in each direction used for calculating the plotted surface.                                                                                                                                                                                                                                                                                                        |
| too.far     | plot grid nodes that are too far from the points defined by the variables given in <code>view</code> can be excluded from the plot. <code>too.far</code> determines what is too far. The grid is scaled into the unit square along with the <code>view</code> variables and then grid nodes more than <code>too.far</code> from the predictor variables are excluded.                       |
| col         | The colours for the facets of the plot. If this is NA then if <code>se&gt;0</code> the facets are transparent, otherwise the colour scheme specified in <code>color</code> is used. If <code>col</code> is not NA then it is used as the facet colour.                                                                                                                                      |
| color       | the colour scheme to use for plots when <code>se&lt;=0</code> . One of "topo", "heat", "cm", "terrain", "gray" or "bw". Schemes "gray" and "bw" also modify the colors used when <code>se&gt;0</code> .                                                                                                                                                                                     |
| contour.col | sets the colour of contours when using <code>plot.type="contour"</code> . Default scheme used if NULL.                                                                                                                                                                                                                                                                                      |
| se          | if less than or equal to zero then only the predicted surface is plotted, but if greater than zero, then 3 surfaces are plotted, one at the predicted values minus <code>se</code> standard errors, one at the predicted values and one at the predicted values plus <code>se</code> standard errors.                                                                                       |
| type        | "link" to plot on linear predictor scale and "response" to plot on the response scale.                                                                                                                                                                                                                                                                                                      |
| plot.type   | one of "contour" or "persp".                                                                                                                                                                                                                                                                                                                                                                |
| zlim        | a two item array giving the lower and upper limits for the z-axis scale. NULL to choose automatically.                                                                                                                                                                                                                                                                                      |
| nCol        | The number of colors to use in color schemes.                                                                                                                                                                                                                                                                                                                                               |
| ...         | other options to pass on to <code>persp</code> , <code>image</code> or <code>contour</code> . In particular <code>ticktype="detailed"</code> will add proper axes labelling to the plots.                                                                                                                                                                                                   |

### Details

The x and y limits are determined by the ranges of the terms named in `view`. If `se<=0` then a single (height colour coded, by default) surface is produced, otherwise three (by default see-through) meshes are produced at mean and +/- `se` standard errors. Parts of the x-y plane too far from data can be excluded by setting `too.far`

All options to the underlying graphics functions can be reset by passing them as extra arguments ...: such supplied values will always over-ride the default values used by `vis.gam`.

**Value**

Simply produces a plot.

**WARNINGS**

The routine can not detect that a variable has been coerced to factor within a model formula, and will therefore fail if such a variable is used as a view variable. When setting default view variables it can not detect this situation either, which can cause failures if the coerced variables are the first, otherwise suitable, variables encountered.

**Examples**

```
library(mgcv)
set.seed(0)
n<-200;sig2<-4
x0 <- runif(n, 0, 1);x1 <- runif(n, 0, 1)
x2 <- runif(n, 0, 1)
y<-x0^2+x1*x2 +runif(n,-0.3,0.3)
g<-gam(y~s(x0,x1,x2))
old.par<-par(mfrow=c(2,2))
display the prediction surface in x0, x1
vis.gam(g,ticktype="detailed",color="heat",theta=-35)
vis.gam(g,se=2,theta=-35) # with twice standard error surfaces
vis.gam(g, view=c("x1","x2"),cond=list(x0=0.75)) # different view
vis.gam(g, view=c("x1","x2"),cond=list(x0=.75),theta=210,phi=40,
 too.far=.07)
..... areas where there is no data are not plotted

contour examples....
vis.gam(g, view=c("x1","x2"),plot.type="contour",color="heat")
vis.gam(g, view=c("x1","x2"),plot.type="contour",color="terrain")
vis.gam(g, view=c("x1","x2"),plot.type="contour",color="topo")
vis.gam(g, view=c("x1","x2"),plot.type="contour",color="cm")

par(old.par)

Examples with factor and "by" variables

fac<-rep(1:4,20)
x<-runif(80)
y<-fac+2*x^2+rnorm(80)*0.1
fac<-factor(fac)
b<-gam(y~fac+s(x))

vis.gam(b,theta=-35,color="heat") # factor example
```

2700

*vis.gam*

```
z<-rnorm(80)*0.4
y<-as.numeric(fac)+3*x^2*z+rnorm(80)*0.1
b<-gam(y~fac+s(x,by=z))

vis.gam(b,theta=-35,color="heat",cond=list(z=1)) # by variable example

vis.gam(b,view=c("z","x"),theta= 35) # plot against by variable
```

# Chapter 25

## The nlme package

---

ACF

*Autocorrelation Function*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: gls and lme.

### Usage

```
ACF(object, maxLag, ...)
```

### Arguments

|        |                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | any object from which an autocorrelation function can be obtained. Generally an object resulting from a model fit, from which residuals can be extracted. |
| maxLag | maximum lag for which the autocorrelation should be calculated.                                                                                           |
| ...    | some methods for this generic require additional arguments.                                                                                               |

### Value

will depend on the method function used; see the appropriate documentation.

## Examples

```
see the method function documentation
```

ACF.gls

*Autocorrelation Function for gls Residuals*

## Description

This method function calculates the empirical autocorrelation function for the residuals from a `gls` fit. If a grouping variable is specified in `form`, the autocorrelation values are calculated using pairs of residuals within the same group; otherwise all possible residual pairs are used. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

## Usage

```
S3 method for class 'gls'
ACF(object, maxLag, resType, form, na.action, ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | an object inheriting from class <code>gls</code> , representing a generalized least squares fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>maxLag</code>    | an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the residuals.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>resType</code>   | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson". |
| <code>form</code>      | an optional one sided formula of the form <code>~ t</code> , or <code>~ t   g</code> , specifying a time covariate <code>t</code> and, optionally, a grouping factor <code>g</code> . The time covariate must be integer valued. When a grouping factor is present in <code>form</code> , the autocorrelations are calculated using residual pairs within the same group. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.                                                   |
| <code>na.action</code> | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>ACF.gls</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                                                                                                                              |
| <code>...</code>       | some methods for this generic require additional arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Value

a data frame with columns `lag` and `ACF` representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class `ACF`.

 weights = varPower(form = ~ pressure))

ACF(fm2Dial.gls, form = ~ 1 | Subject)
```

**ACF.lme**

*Autocorrelation Function for lme Residuals*

## Description

This method function calculates the empirical autocorrelation function for the within-group residuals from an `lme` fit. The autocorrelation values are calculated using pairs of residuals within the innermost group level. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

## Usage

```
S3 method for class 'lme'
ACF(object, maxLag, resType, ...)
```

## Arguments

- |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>maxLag</code>  | an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the within-group residuals.                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>resType</code> | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson". |
| <code>...</code>     | some methods for this generic require additional arguments – not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Value**

a data frame with columns lag and ACF representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class ACF.

plot(ACF.fm1Over, alpha=0.01)
```

**Description**

The *Alfalfa* data frame has 72 rows and 4 columns.

**Format**

This data frame contains the following columns:

- Variety** a factor with levels Cossack, Ladak, and Ranger  
**Date** a factor with levels None S1 S20 07  
**Block** a factor with levels 1 2 3 4 5 6  
**Yield** a numeric vector

## Details

These data are described in Snedecor and Cochran (1980) as an example of a split-plot design. The treatment structure used in the experiment was a  $3 \times 4$  full factorial, with three varieties of alfalfa and four dates of third cutting in 1943. The experimental units were arranged into six blocks, each subdivided into four plots. The varieties of alfalfa (*Cossac*, *Ladak*, and *Ranger*) were assigned randomly to the blocks and the dates of third cutting (*None*, *S1*—September 1, *S20*—September 20, and *O7*—October 7) were randomly assigned to the plots. All four dates were used on each block.

allCoef

*Extract Coefficients from a Set of Objects*

---

## Description

The extractor function is applied to each object in ..., with the result being converted to a vector. A map attribute is included to indicate which pieces of the returned vector correspond to the original objects in dots.

## Usage

`allCoef(..., extract)`

## Arguments

|         |                                                                                                                            |
|---------|----------------------------------------------------------------------------------------------------------------------------|
| ...     | objects to which extract will be applied. Generally these will be model components, such as corStruct and varFunc objects. |
| extract | an optional extractor function. Defaults to <code>coef</code> .                                                            |

## Value

a vector with all elements, generally coefficients, obtained by applying `extract` to the objects in ...

```
cs1 <- corAR1(0.1)
vf1 <- varPower(0.5)
allCoef(cs1, vf1)
```

---

anova.gls*Compare Likelihoods of Fitted Objects*

---

**Description**

When only one fitted model object is present, a data frame with the sums of squares, numerator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when Terms and L are NULL), a combination of model terms (when Terms is not NULL), or linear combinations of the model coefficients (when L is not NULL). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If test=TRUE, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic, with the associated p-value is included in the returned data frame.

**Usage**

```
S3 method for class 'gls'
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
```

**Arguments**

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object      | a fitted model object inheriting from class gls, representing a generalized least squares fit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ...         | other optional fitted model objects inheriting from classes gls, gnls, lm, lme, lmList, nlme, nlsList, or nls.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| test        | an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by object and the objects in .... Defaults to TRUE.                                                                                                                                                                                                                                                                                                                                                                                       |
| type        | an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential". |
| adjustSigma | an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.                                                                                                                                                                                                                               |
| Terms       | an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.                                                                                                                           |
| L           | an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will                                                                                                                                                                                                                                    |

be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.

**verbose** an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.

### Value

a data frame inheriting from class `anova.lme`.

### Note

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

**anova.lme***Compare Likelihoods of Fitted Objects***Description**

When only one fitted model object is present, a data frame with the sums of squares, numerator degrees of freedom, denominator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when `Terms` and `L` are `NULL`), a combination of model terms (when `Terms` is not `NULL`), or linear combinations of the model coefficients (when `L` is not `NULL`). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If `test=TRUE`, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic, with the associated p-value is included in the returned data frame.

**Usage**

```

S3 method for class 'lme'
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
S3 method for class 'anova.lme'
print(x, verbose, ...)

```

**Arguments**

- |                     |                                                                                                                                                                                                                                |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | a fitted model object inheriting from class <code>lme</code> , representing a mixed-effects model.                                                                                                                             |
| <code>...</code>    | other optional fitted model objects inheriting from classes <code>gls</code> , <code>gnls</code> , <code>lm</code> , <code>lme</code> , <code>lmlist</code> , <code>nlme</code> , <code>nlsList</code> , or <code>nls</code> . |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| test        | an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by object and the objects in .... Defaults to TRUE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| type        | an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential".                                                                           |
| adjustSigma | an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.                                                                                                                                                                                                                                                                                                         |
| Terms       | an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.                                                                                                                                                                                                     |
| L           | an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL. |
| x           | an object inheriting from class anova.lme                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| verbose     | an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### Value

a data frame inheriting from class anova.lme.

### Note

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

---

**as.matrix.corStruct**     *Matrix of a corStruct Object*

---

## Description

This method function extracts the correlation matrix, or list of correlation matrices, associated with object.

## Usage

```
S3 method for class 'corStruct'
as.matrix(x, ...)
```

## Arguments

x                an object inheriting from class `corStruct`, representing a correlation structure.  
...                further arguments passed from other methods.

## Value

If the correlation structure includes a grouping factor, the returned value will be a list with components given by the correlation matrices for each group. Otherwise, the returned value will be a matrix representing the correlation structure associated with object.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

cst1 <- Initialize(cst1, data = Orthodont)
as.matrix(cst1)
```

**as.matrix.pdMat**      *Matrix of a pdMat Object*

### Description

This method function extracts the positive-definite matrix represented by *x*.

### Usage

```
S3 method for class 'pdMat'
as.matrix(x, ...)
```

### Arguments

- x*                an object inheriting from class *pdMat*, representing a positive-definite matrix.
- ...                further arguments passed from other methods.

### Value

a matrix corresponding to the positive-definite matrix represented by *x*.

### Author(s)

**as.matrix.reStruct**      *Matrices of an reStruct Object*

### Description

This method function extracts the positive-definite matrices corresponding to the *pdMat* elements of *object*.

### Usage

```
S3 method for class 'reStruct'
as.matrix(x, ...)
```

**Arguments**

- x an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of `pdMat` objects.
- ... further arguments passed from other methods.

**Value**

a list with components given by the positive-definite matrices corresponding to the elements of object.

*Combine Formulas of a Set of Objects*

**Description**

The names of all variables used in the formulas extracted from the objects defined in ... are converted into a single linear formula, with the variables names separated by +.

**Usage**

```
asOneFormula(..., omit)
```

**Arguments**

- ... objects, or lists of objects, from which a formula can be extracted.
- omit an optional character vector with the names of variables to be omitted from the returned formula. Defaults to c(".", "pi").

**Value**

a one-sided linear formula with all variables named in the formulas extracted from the objects in ..., except the ones listed in `omit`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
asOneFormula(y ~ x + z | g, list(~ w, ~ t * sin(2 * pi)))
```

---

Assay

*Bioassay on Cell Culture Plate*

---

**Description**

The Assay data frame has 60 rows and 4 columns.

**Format**

This data frame contains the following columns:

- Block** an ordered factor with levels 2 < 1 identifying the block where the wells are measured.  
**sample** a factor with levels a to f identifying the sample corresponding to the well.  
**dilut** a factor with levels 1 to 5 indicating the dilution applied to the well  
**logDens** a numeric vector of the log-optical density

**Details**

These data, courtesy of Rich Wolfe and David Lansky from Searle, Inc., come from a bioassay run on a 96-well cell culture plate. The assay is performed using a split-block design. The 8 rows on the plate are labeled A–H from top to bottom and the 12 columns on the plate are labeled 1–12 from left to right. Only the central 60 wells of the plate are used for the bioassay (the intersection of rows B–G and columns 2–11). There are two blocks in the design: Block 1 contains columns 2–6 and Block 2 contains columns 7–11. Within each block, six samples are assigned randomly to rows and five (serial) dilutions are assigned randomly to columns. The response variable is the logarithm of the optical density. The cells are treated with a compound that they metabolize to produce the stain. Only live cells can make the stain, so the optical density is a measure of the number of cells that are alive and healthy.

---

**asTable***Convert groupedData to a matrix*

---

**Description**

Create a tabular representation of the response in a balanced groupedData object.

**Usage**

```
asTable(object)
```

**Arguments**

|        |                               |
|--------|-------------------------------|
| object | A balanced groupedData object |
|--------|-------------------------------|

**Details**

A balanced groupedData object can be represented as a matrix or table of response values corresponding to the values of a primary covariate for each level of a grouping factor. This function creates such a matrix representation of the data in object.

**Value**

A matrix. The data in the matrix are the values of the response. The columns correspond to the distinct values of the primary covariate and are labelled as such. The rows correspond to the distinct levels of the grouping factor and are labelled as such.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

augPred*Augmented Predictions*

---

**Description**

Predicted values are obtained at the specified values of `primary`. If `object` has a grouping structure (i.e. `getGroups(object)` is not `NULL`), predicted values are obtained for each group. If `level` has more than one element, predictions are obtained for each level of the `max(level)` grouping factor. If other covariates besides `primary` are used in the prediction model, their average (numeric covariates) or most frequent value (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

**Usage**

```
augPred(object, primary, minimum, maximum, length.out, ...)

S3 method for class 'lme'
augPred(object, primary = NULL,
 minimum = min(primary), maximum = max(primary),
 length.out = 51, level = Q, ...)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>     | a fitted model object from which predictions can be extracted, using a <code>predict</code> method.                                                                                                                                                                                           |
| <code>primary</code>    | an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate <code>object</code> (using <code>getCovariate</code> ), it will be used as <code>primary</code> . |
| <code>minimum</code>    | an optional lower limit for the primary covariate. Defaults to <code>min(primary)</code> .                                                                                                                                                                                                    |
| <code>maximum</code>    | an optional upper limit for the primary covariate. Defaults to <code>max(primary)</code> .                                                                                                                                                                                                    |
| <code>length.out</code> | an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.                                                                                                                                                                         |
| <code>level</code>      | an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.                                                             |
| <code>...</code>        | some methods for the generic may require additional arguments.                                                                                                                                                                                                                                |

**Value**

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if `object` does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: `original` for the observed values and `predicted` (single or no grouping factor) or `predict.groupVar` (multiple levels of grouping), with `groupVar` replaced by the actual grouping variable name (`fixed` is used for population predictions). The returned object inherits from class `augPred`.

**Note**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

```

---

balancedGrouped      *Create a groupedData object from a matrix*

---

**Description**

Create a groupedData object from a data matrix. This function can be used only with balanced data. The opposite conversion, from a groupedData object to a matrix, is done with `asTable`.

**Usage**

```
balancedGrouped(form, data, labels=NULL, units=NULL)
```

**Arguments**

- |        |                                                                                                                                                                                                                                                                                                      |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| form   | A formula of the form $y \sim x \mid g$ giving the name of the response, the primary covariate, and the grouping factor.                                                                                                                                                                             |
| data   | A matrix or data frame containing the values of the response grouped according to the levels of the grouping factor (rows) and the distinct levels of the primary covariate (columns). The dimnames of the matrix are used to construct the levels of the grouping factor and the primary covariate. |
| labels | an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either label can be omitted.                                                         |
| units  | an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either units string can be omitted.                                        |

**Value**

A balanced groupedData object.

bdf

*Language scores*

## Description

The bdf data frame has 2287 rows and 25 columns of language scores from grade 8 pupils in elementary schools in The Netherlands.

## Usage

`data(bdf)`

## Format

**schoolNR** a factor denoting the school.

**pupilNR** a factor denoting the pupil.

**IQ.verb** a numeric vector of verbal IQ scores

**IQ.perf** a numeric vector of IQ scores.

**sex** Sex of the student.

**Minority** a factor indicating if the student is a member of a minority group.

**repeatgr** an ordered factor indicating if one or more grades have been repeated.

**aritPRET** a numeric vector

**classNR** a numeric vector

**aritPOST** a numeric vector

**langPRET** a numeric vector

**langPOST** a numeric vector

**ses** a numeric vector of socioeconomic status indicators.  
**denomina** a factor indicating of the school is a public school, a Protestant private school, a Catholic private school, or a non-denominational private school.  
**schoolSES** a numeric vector  
**satiprin** a numeric vector  
**natitest** a factor with levels 0 and 1  
**meetings** a numeric vector  
**currmeet** a numeric vector  
**mixedgra** a factor indicating if the class is a mixed-grade class.  
**percmino** a numeric vector  
**aritdiff** a numeric vector  
**homework** a numeric vector  
**classsiz** a numeric vector  
**groupsiz** a numeric vector

summary(bdf)
```

---

|            |                                                 |
|------------|-------------------------------------------------|
| BodyWeight | <i>Rat weight over time for different diets</i> |
|------------|-------------------------------------------------|

---

### Description

The BodyWeight data frame has 176 rows and 4 columns.

### Format

This data frame contains the following columns:

**weight** a numeric vector giving the body weight of the rat (grams).  
**Time** a numeric vector giving the time at which the measurement is made (days).  
**Rat** an ordered factor with levels  $2 < 3 < 4 < 1 < 8 < 5 < 6 < 7 < 11 < 9 < 10 < 12 < 13 < 15 < 14 < 16$  identifying the rat whose weight is measured.  
**Diet** a factor with levels 1 to 3 indicating the diet that the rat receives.

## Details

Hand and Crowder (1996) describe data on the body weights of rats measured over 64 days. These data also appear in Table 2.4 of Crowder and Hand (1990). The body weights of the rats (in grams) are measured on day 1 and every seven days thereafter until day 64, with an extra measurement on day 44. The experiment started several weeks before “day 1.” There are three groups of rats, each on a different diet.

Cefamandole

*Pharmacokinetics of Cefamandole*

## Description

The Cefamandole data frame has 84 rows and 3 columns.

## Format

This data frame contains the following columns:

- Subject** a factor giving the subject from which the sample was drawn.
- Time** a numeric vector giving the time at which the sample was drawn (minutes post-injection).
- conc** a numeric vector giving the observed plasma concentration of cefamandole (mcg/ml).

## Details

Davidian and Giltinan (1995, 1.1, p. 2) describe data obtained during a pilot study to investigate the pharmacokinetics of the drug cefamandole. Plasma concentrations of the drug were measured on six healthy volunteers at 14 time points following an intravenous dose of 15 mg/kg body weight of cefamandole.

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all `pdMat`, `corStruct`, and `varFunc` classes, `reStruct`, and `modelStruct`.

### Usage

```
coef(object, ...) <- value
```

### Arguments

|        |                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------|
| object | any object representing a fitted model, or, by default, any object with a <code>coef</code> component. |
| ...    | some methods for this generic function may require additional arguments.                               |
| value  | a value to be assigned to the coefficients associated with <code>object</code> .                       |

### Value

will depend on the method function; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

### See Also

[coef](#)

### Examples

```
see the method function documentation
```

---

|                |                                           |
|----------------|-------------------------------------------|
| coef.corStruct | <i>Coefficients of a corStruct Object</i> |
|----------------|-------------------------------------------|

---

### Description

This method function extracts the coefficients associated with the correlation structure represented by `object`.

### Usage

```
S3 method for class 'corStruct'
coef(object, unconstrained, ...)
S3 replacement method for class 'corStruct'
coef(object, ...) <- value
```

**Arguments**

- object** an object inheriting from class `corStruct`, representing a correlation structure.
- unconstrained** a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE.
- value** a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef{object}` and must be given in unconstrained form.
- ...** some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the coefficients corresponding to `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`. `Object` must be initialized (using `Initialize`) before new values can be assigned to its coefficients.

**Author(s)**

José Pinheiro and Douglas Bates

**References**

**Examples**

```
cst1 <- corARMA(p = 1, q = 1)
coef(cst1)
```

`coef.gnls`

*Extract gnls Coefficients*

**Description**

The estimated coefficients for the nonlinear model represented by `object` are extracted.

**Usage**

```
S3 method for class 'gnls'
coef(object, ...)
```

**Arguments**

- object            an object inheriting from class `gnls`, representing a generalized nonlinear least squares fitted model.  
...                some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the estimated coefficients for the nonlinear model represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**See Also**

[gnls](#)

**Examples**

```
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
 weights = varPower())
coef(fm1)
```

---

coef.lme

*Extract lme Coefficients*

---

**Description**

The estimated coefficients at level  $i$  are obtained by adding together the fixed effects estimates and the corresponding random effects estimates at grouping levels less or equal to  $i$ . The resulting estimates are returned as a data frame, with rows corresponding to groups and columns to coefficients. Optionally, the returned data frame may be augmented with covariates summarized over groups.

**Usage**

```
S3 method for class 'lme'
coef(object, augFrame, level, data, which, FUN,
 omitGroupingFactor, subset, ...)
```

**Arguments**

- object            an object inheriting from class `lme`, representing a fitted linear mixed-effects model.  
augFrame          an optional logical value. If TRUE, the returned data frame is augmented with variables defined in `data`; else, if FALSE, only the coefficients are returned. Defaults to FALSE.  
level             an optional positive integer giving the level of grouping to be used in extracting the coefficients from an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| data                            | an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| which                           | an optional positive integer or character vector specifying which columns of data should be used in the augmentation of the returned data frame. Defaults to all columns in <code>data</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| FUN                             | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing <code>data</code> by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable. |
| <code>omitGroupingFactor</code> | an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary of <code>data</code> but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| subset                          | an optional expression specifying a subset                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ...                             | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### Value

a data frame inheriting from class `coef.lme` with the estimated coefficients at level `level` and, optionally, other covariates summarized over groups. The returned object also inherits from classes `ranef.lme` and `data.frame`.

### Examples

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
coef(fm1)
coef(fm1, augFrame = TRUE)
```

---

coef.lmList*Extract lmList Coefficients*

## Description

The coefficients of each `lm` object in the object list are extracted and organized into a data frame, with rows corresponding to the `lm` components and columns corresponding to the coefficients. Optionally, the returned data frame may be augmented with covariates summarized over the groups associated with the `lm` components.

## Usage

```
S3 method for class 'lmList'
coef(object, augFrame, data, which, FUN,
 omitGroupingFactor, ...)
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| object             | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| augFrame           | an optional logical value. If TRUE, the returned data frame is augmented with variables defined in the data frame used to produce <code>object</code> ; else, if FALSE, only the coefficients are returned. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| data               | an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame</code> = TRUE. Defaults to the data frame used to fit <code>object</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| which              | an optional positive integer or character vector specifying which columns of the data frame used to produce <code>object</code> should be used in the augmentation of the returned data frame. Defaults to all variables in the data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| FUN                | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing the data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable. |
| omitGroupingFactor | an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of <code>data</code> but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ...                | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Value**

a data frame inheriting from class `coef.lmList` with the estimated coefficients for each `lm` component of `object` and, optionally, other covariates summarized over the groups corresponding to the `lm` components. The returned object also inherits from classes `ranef.lmList` and `data.frame`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

**See Also**

`lmList`, `fixed.effects.lmList`, `ranef.lmList`, `plot.ranef.lmList`, `gsummary`

**Examples**

```
fm1 <- lmList(distance ~ age|Subject, data = Orthodont)
coef(fm1)
coef(fm1, augFrame = TRUE)
```

`coef.modelStruct`      *Extract modelStruct Object Coefficients*

**Description**

This method function extracts the coefficients associated with each component of the `modelStruct` list.

**Usage**

```
S3 method for class 'modelStruct'
coef(object, unconstrained, ...)
S3 replacement method for class 'modelStruct'
coef(object, ...) <- value
```

**Arguments**

|                            |                                                                                                                                                                                                                                                                        |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>        | an object inheriting from class <code>modelStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects.                                                                                                   |
| <code>unconstrained</code> | a logical value. If <code>TRUE</code> the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If <code>FALSE</code> the coefficients are returned in "natural", possibly constrained, form. Defaults to <code>TRUE</code> . |
| <code>value</code>         | a vector with the replacement values for the coefficients associated with <code>object</code> . It must be a vector with the same length of <code>coef{object}</code> and must be given in unconstrained form.                                                         |
| <code>...</code>           | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                              |

**Value**

a vector with all coefficients corresponding to the components of object.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of object to value. Object must be initialized (using [Initialize](#)) before new values can be assigned to its coefficients.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[Initialize](#)

**Examples**

```
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
 corStruct = corAR1(0.3))
coef(lms1)
```

coef.pdMat

*pdMat Object Coefficients*

**Description**

This method function extracts the coefficients associated with the positive-definite matrix represented by object.

**Usage**

```
S3 method for class 'pdMat'
coef(object, unconstrained, ...)
S3 replacement method for class 'pdMat'
coef(object, ...) <- value
```

**Arguments**

- object an object inheriting from class pdMat, representing a positive-definite matrix.
- unconstrained a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the upper triangular elements of the positive-definite matrix represented by object are returned. Defaults to TRUE.
- value a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of coef{object} and must be given in unconstrained form.
- ... some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the coefficients corresponding to `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

**Author(s)**

José Pinheiro and Douglas Bates

**Examples**

```
coef(pdSymm(diag(3)))
```

|                            |                                     |
|----------------------------|-------------------------------------|
| <code>coef.reStruct</code> | <i>reStruct Object Coefficients</i> |
|----------------------------|-------------------------------------|

**Description**

This method function extracts the coefficients associated with the positive-definite matrix represented by `object`.

**Usage**

```
S3 method for class 'reStruct'
coef(object, unconstrained, ...)
S3 replacement method for class 'reStruct'
coef(object, ...) <- value
```

**Arguments**

- `object` an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of `pdMat` objects.
- `unconstrained` a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE.
- `value` a vector with the replacement values for the coefficients associated with `object`. It must be a vector with the same length of `coef(object)` and must be given in unconstrained form.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the coefficients corresponding to object.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of object to value.

```
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
 B = pdDiag(2 * diag(4), form = ~Educ)))
coef(rs1)
```

---

coef.varFunc

*varFunc Object Coefficients*

---

**Description**

This method function extracts the coefficients associated with the variance function structure represented by object.

**Usage**

```
S3 method for class 'varFunc'
coef(object, unconstrained, allCoef, ...)
S3 replacement method for class 'varIdent'
coef(object, ...) <- value
```

**Arguments**

- |               |                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object        | an object inheriting from class varFunc representing a variance function structure.                                                                                                                                                                          |
| unconstrained | a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", generally constrained form. Defaults to TRUE.                               |
| allCoef       | a logical value. If FALSE only the coefficients which may vary during the optimization are returned. If TRUE all coefficients are returned. Defaults to FALSE.                                                                                               |
| value         | a vector with the replacement values for the coefficients associated with object. It must be have the same length of coef{object} and must be given in unconstrained form. Object must be initialized before new values can be assigned to its coefficients. |
| ...           | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                    |

**Value**

a vector with the coefficients corresponding to object.

collapse

*Collapse According to Groups*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Currently, only a `groupedData` method is available.

**Usage**

```
collapse(object, ...)
```

**Arguments**

|        |                                                                |
|--------|----------------------------------------------------------------|
| object | an object to be collapsed, usually a data frame.               |
| ...    | some methods for the generic may require additional arguments. |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

[collapse.groupedData](#)

## Examples

```
see the method function documentation
```

`collapse.groupedData` *Collapse a groupedData Object*

## Description

If object has a single grouping factor, it is returned unchanged. Else, it is summarized by the values of the `displayLevel` grouping factor (or the combination of its values and the values of the covariate indicated in `preserve`, if any is present). The collapsed data is used to produce a new `groupedData` object, with grouping factor given by the `displayLevel` factor.

## Usage

```
S3 method for class 'groupedData'
collapse(object, collapseLevel, displayLevel,
 outer, inner, preserve, FUN, subset, ...)
```

## Arguments

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>        | an object inheriting from class <code>groupedData</code> , generally with multiple grouping factors.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>collapseLevel</code> | an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.                                                                                                                                                                                                                                                                                                                                 |
| <code>displayLevel</code>  | an optional positive integer or character string indicating the grouping level to use as the grouping factor for the collapsed data. Default is <code>collapseLevel</code> .                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>outer</code>         | an optional logical value or one-sided formula, indicating covariates that are outer to the <code>displayLevel</code> grouping factor. If equal to TRUE, the <code>displayLevel</code> element <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used. |
| <code>inner</code>         | an optional logical value or one-sided formula, indicating a covariate that is inner to the <code>displayLevel</code> grouping factor. If equal to TRUE, <code>attr(object, "outer")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.                                                                                                                                                                           |
| <code>preserve</code>      | an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the <code>collapseLevel</code> grouping factor. The collapsing factor is obtained by pasting together the levels of the <code>collapseLevel</code> grouping factor and the values of the covariate to be preserved. Default is NULL, meaning that no covariates need to be preserved.                                                                                                                                                  |
| <code>FUN</code>           | an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in <code>object</code> that vary within the groups defined by <code>collapseLevel</code> . Invariant variables are always summarized by group using the unique value that they assume                                                                                                                                                                                                                      |

within that group. If FUN is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the data such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

- |        |                                                                                                                                                                                                                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| subset | an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be preserved in the collapsed data. Default is NULL, meaning that all levels are used. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                           |

### **Value**

a groupedData object with a single grouping factor given by the displayLevel grouping factor, resulting from collapsing object over the levels of the collapseLevel grouping factor.

### **Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### **See Also**

[groupedData](#), [plot.nmGroupedData](#)

### **Examples**

```
collapsing by Dog
collapse(Pixel, collapse = 1) # same as collapse(Pixel, collapse = "Dog")
```

[compareFits](#)

*Compare Fitted Objects*

### **Description**

The columns in object1 and object2 are put together in matrices which allow direct comparison of the individual elements for each object. Missing columns in either object are replaced by NAs.

### **Usage**

```
compareFits(object1, object2, which)
```

**Arguments****object1, object2**

data frames, or matrices, with the same row names, but possibly different column names. These will usually correspond to coefficients from fitted objects with a grouping structure (e.g. `lme` and `lmList` objects).

**which**

an optional integer or character vector indicating which columns in `object1` and `object2` are to be used in the returned object. Defaults to all columns.

**Value**

a three-dimensional array, with the third dimension given by the number of unique column names in either `object1` or `object2`. To each column name there corresponds a matrix with as many rows as the rows in `object1` and two columns, corresponding to `object1` and `object2`. The returned object inherits from class `compareFits`.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**See Also**

[plot.compareFits](#), [pairs.compareFits](#), [comparePred](#), [coef](#), [random.effects](#)

**Examples**

```
fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
compareFits(coef(fm1), coef(fm2))
```

---

**comparePred***Compare Predictions*

---

**Description**

Predicted values are obtained at the specified values of `primary` for each object. If either `object1` or `object2` have a grouping structure (i.e. `getGroups(object)` is not `NULL`), predicted values are obtained for each group. When both objects determine groups, the group levels must be the same. If other covariates besides `primary` are used in the prediction model, their group-wise averages (numeric covariates) or most frequent values (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

**Usage**

```
comparePred(object1, object2, primary, minimum, maximum,
 length.out, level, ...)
```

**Arguments**

|                               |                                                                                                                                                                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object1, object2</code> | fitted model objects, from which predictions can be extracted using the <code>predict</code> method.                                                                                                                                                                                  |
| <code>primary</code>          | an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate the objects (using <code>getCovariate</code> ), it will be used as <code>primary</code> . |
| <code>minimum</code>          | an optional lower limit for the primary covariate. Defaults to <code>min(primary)</code> , after <code>primary</code> is evaluated in the data used in fitting <code>object1</code> .                                                                                                 |
| <code>maximum</code>          | an optional upper limit for the primary covariate. Defaults to <code>max(primary)</code> , after <code>primary</code> is evaluated in the data used in fitting <code>object1</code> .                                                                                                 |
| <code>length.out</code>       | an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.                                                                                                                                                                 |
| <code>level</code>            | an optional integer specifying the desired prediction level. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Only one level can be specified. Defaults to the innermost level.                            |
| <code>...</code>              | some methods for the generic may require additional arguments.                                                                                                                                                                                                                        |

**Value**

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if `object` does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: the objects' names are used to classify the predicted values and `original` is used for the observed values. The returned object inherits from classes `comparePred` and `augPred`.

**Note**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**See Also**

[augPred](#), [getGroups](#)

**Examples**

```
fm1 <- lme(distance ~ age * Sex, data = Orthodont, random = ~ age)
fm2 <- update(fm1, distance ~ age)
comparePred(fm1, fm2, length.out = 2)
```

---

**corAR1***AR(1) Correlation Structure*

---

## Description

This function is a constructor for the `corAR1` class, representing an autocorrelation structure of order 1. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

## Usage

```
corAR1(value, form, fixed)
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code> | the value of the lag 1 autocorrelation, which must be between -1 and 1. Defaults to 0 (no autocorrelation).                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>form</code>  | a one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| <code>fixed</code> | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                   |

## Value

```

## Description

This function is a constructor for the `corARMA` class, representing an autocorrelation-moving average correlation structure of order  $(p, q)$ . Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

## Usage

```
corARMA(value, form, p, q, fixed)
```

**Arguments**

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>value</b> | a vector with the values of the autoregressive and moving average parameters, which must have length $p + q$ and all elements between -1 and 1. Defaults to a vector of zeros, corresponding to uncorrelated observations.                                                                                                                                                                                                                                                                                                                                            |
| <b>form</b>  | a one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <b>form</b> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| <b>p, q</b>  | non-negative integers specifying respectively the autoregressive order and the moving average order of the ARMA structure. Both default to 0.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>fixed</b> | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                             |

**corCAR1***Continuous AR(1) Correlation Structure***Description**

This function is a constructor for the `corCAR1` class, representing an autocorrelation structure of order 1, with a continuous time covariate. Objects created using this constructor must be later initialized using the appropriate `Initialize` method.

**Usage**

```
corCAR1(value, form, fixed)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code> | the correlation between two observations one unit of time apart. Must be between 0 and 1. Defaults to 0.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>form</code>  | a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . Covariates for this correlation structure need not be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| <code>fixed</code> | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                         |

**Value**

an object of class `corCAR1`, representing an autocorrelation structure of order 1, with a continuous time covariate.

**Author(s)**

## Description

Standard classes of correlation structures (`corStruct`) available in the `nlme` library.

## Value

Available standard classes:

|                          |                                                                                                                    |
|--------------------------|--------------------------------------------------------------------------------------------------------------------|
| <code>corAR1</code>      | autoregressive process of order 1.                                                                                 |
| <code>corARMA</code>     | autoregressive moving average process, with arbitrary orders for the autoregressive and moving average components. |
| <code>corCAR1</code>     | continuous autoregressive process (AR(1) process for a continuous time covariate).                                 |
| <code>corCompSymm</code> | compound symmetry structure corresponding to a constant correlation.                                               |
| <code>corExp</code>      | exponential spatial correlation.                                                                                   |
| <code>corGaus</code>     | Gaussian spatial correlation.                                                                                      |
| <code>corLin</code>      | linear spatial correlation.                                                                                        |
| <code>corRatio</code>    | Rational quadratics spatial correlation.                                                                           |
| <code>corSpher</code>    | spherical spatial correlation.                                                                                     |
| <code>corSymm</code>     | general correlation matrix, with no additional structure.                                                          |

**Note**

Users may define their own `corStruct` classes by specifying a constructor function and, at a minimum, methods for the functions `corMatrix` and `coef`. For examples of these functions, see the methods for classes `corSymm` and `corAR1`.

*corCompSymm*

*Compound Symmetry Correlation Structure*

**Description**

This function is a constructor for the `corCompSymm` class, representing a compound symmetry structure corresponding to uniform correlation. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corCompSymm(value, form, fixed)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code> | the correlation between any two correlated observations. Defaults to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>form</code>  | a one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| <code>fixed</code> | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                |

**Value**

an object of class `corCompSymm`, representing a compound symmetry correlation structure.

cs1CompSymm <- Initialize(cs1CompSymm, data = Orthodont)
corMatrix(cs1CompSymm)
```

## Description

This function is a constructor for the `corExp` class, representing an exponential spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $\exp(-r/d)$  when no nugget effect is present and  $(1 - n)\exp(-r/d)$  when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

## Usage

```
corExp(value, form, nugget, metric, fixed)
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code> | an optional vector with the parameter values in constrained form. If <code>nugget</code> is FALSE, <code>value</code> can have only one element, corresponding to the "range" of the exponential correlation structure, which must be greater than zero. If <code>nugget</code> is TRUE, meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Defaults to `numeric(0)`, which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>form</code>   | a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| <code>nugget</code> | an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>metric</code> | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                                |
| <code>fixed</code>  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                 |

### Value

an object of class `corExp`, also inheriting from class `corSpatial`, representing an exponential spatial correlation structure.

---

**corFactor***Factor of a Correlation Matrix*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all `corStruct` classes.

**Usage**

```
corFactor(object, ...)
```

**Arguments**

- |        |                                                                      |
|--------|----------------------------------------------------------------------|
| object | an object from which a correlation matrix can be extracted.          |
| ...    | some methods for this generic function require additional arguments. |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`corFactor.corStruct`, `recalc.corStruct`

**Examples**

```
see the method function documentation
```

`corFactor.corStruct`     *Factor of a corStruct Object Matrix*

**Description**

This method function extracts a transpose inverse square-root factor, or a series of transpose inverse square-root factors, of the correlation matrix, or list of correlation matrices, represented by `object`. Letting  $\Sigma$  denote a correlation matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This method extracts  $L^{-t}$ .

**Usage**

```
S3 method for class 'corStruct'
corFactor(object, ...)
```

**Arguments**

- |                     |                                                                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>corStruct</code> representing a correlation structure, which must have been initialized (using <code>Initialize</code> ). |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                       |

**Value**

If the correlation structure does not include a grouping factor, the returned value will be a vector with a transpose inverse square-root factor of the correlation matrix associated with `object` stacked column-wise. If the correlation structure includes a grouping factor, the returned value will be a vector with transpose inverse square-root factors of the correlation matrices for each group, stacked by group and stacked column-wise within each group.

**Note**

This method function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `corMatrix` method function can be used to obtain transpose inverse square-root factors in matrix form.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
cs1 <- corAR1(form = ~1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
corFactor(cs1)
```

corGaus

*Gaussian Correlation Structure*

## Description

This function is a constructor for the `corGaus` class, representing a Gaussian spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $\exp(-(r/d)^2)$  when no nugget effect is present and  $(1-n) \exp(-(r/d)^2)$  when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate ‘Initialize’ method.

## Usage

```
corGaus(value, form, nugget, metric, fixed)
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code>  | an optional vector with the parameter values in constrained form. If <code>nugget</code> is FALSE, <code>value</code> can have only one element, corresponding to the "range" of the Gaussian correlation structure, which must be greater than zero. If <code>nugget</code> is TRUE, meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| <code>form</code>   | a one sided formula of the form $\sim S1+\dots+Sp$ , or $\sim S1+\dots+Sp \mid g$ , specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.                                                                                                                                                                                                                                                                 |
| <code>nugget</code> | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>metric</code> | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>fixed</code>  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Value**

an object of class `corGaus`, also inheriting from class `corSpatial`, representing a Gaussian spatial correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

fm3BW.lme <- update(fm2BW.lme,
 correlation = corExp(form = ~ Time))
p. 249
fm8BW.lme <- update(fm3BW.lme, correlation = corGaus(form = ~ Time))
```

**Description**

This function is a constructor for the `corLin` class, representing a linear spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r < d$  apart is  $1 - (r/d)$  when no nugget effect is present and  $(1 - n)(1 - (r/d))$  when a nugget effect is assumed. If  $r \geq d$  the correlation is zero. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

`corLin(value, form, nugget, metric, fixed)`

**Arguments**

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>value</b>  | an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the linear correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| <b>form</b>   | a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.                                                                                                                                                                                                          |
| <b>nugget</b> | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>metric</b> | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                                                                                                                                                                                                                    |
| <b>fixed</b>  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Value**

an object of class corLin, also inheriting from class corSpatial, representing a linear spatial correlation structure.

```

## *corMatrix*

### *Extract Correlation Matrix*

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all *corStruct* classes.

## Usage

```
corMatrix(object, ...)
```

## Arguments

- |        |                                                                      |
|--------|----------------------------------------------------------------------|
| object | an object for which a correlation matrix can be extracted.           |
| ...    | some methods for this generic function require additional arguments. |

## Value

will depend on the method function used; see the appropriate documentation.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[corMatrix.corStruct](#), [corMatrix.pdMat](#)

## Examples

```
see the method function documentation
```

---

corMatrix.corStruct     *Matrix of a corStruct Object*

---

## Description

This method function extracts the correlation matrix (or its transpose inverse square-root factor), or list of correlation matrices (or their transpose inverse square-root factors) corresponding to covariate and object. Letting  $\Sigma$  denote a correlation matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . When `corr = FALSE`, this method extracts  $L^{-t}$ .

## Usage

```
S3 method for class 'corStruct'
corMatrix(object, covariate, corr, ...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | an object inheriting from class <code>corStruct</code> representing a correlation structure.                                                                                                                                                                                                                                                   |
| covariate | an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to <code>getCovariate(object)</code> .                                                                                                                  |
| corr      | a logical value. If <code>TRUE</code> the function returns the correlation matrix, or list of correlation matrices, represented by <code>object</code> . If <code>FALSE</code> the function returns a transpose inverse square-root of the correlation matrix, or a list of transpose inverse square-root factors of the correlation matrices. |
| ...       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                      |

## Value

If `covariate` is a vector (matrix), the returned value will be an array with the corresponding correlation matrix (or its transpose inverse square-root factor). If the `covariate` is a list of vectors (matrices), the returned value will be a list with the correlation matrices (or their transpose inverse square-root factors) corresponding to each component of `covariate`.

**corMatrix.pdMat***Extract Correlation Matrix from a pdMat Object*

## Description

The correlation matrix corresponding to the positive-definite matrix represented by object is obtained.

## Usage

```
S3 method for class 'pdMat'
corMatrix(object, ...)
```

## Arguments

- |               |                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------|
| <b>object</b> | an object inheriting from class <code>pdMat</code> , representing a positive definite matrix. |
| <b>...</b>    | some methods for this generic require additional arguments. None are used in this method.     |

## Value

the correlation matrix corresponding to the positive-definite matrix represented by object.

**corMatrix.reStruct**      *Extract Correlation Matrix from Components of an reStruct Object*

---

**Description**

This method function extracts the correlation matrices corresponding to the pdMat elements of object.

**Usage**

```
S3 method for class 'reStruct'
corMatrix(object, ...)
```

**Arguments**

object      an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of `pdMat` objects.  
...      some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with components given by the correlation matrices corresponding to the elements of object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

rs1 <- reStruct(pdSymm(diag(3), ~age+Sex, data = Orthodont))
corMatrix(rs1)
```

**corNatural***General correlation in natural parameterization*

## Description

This function is a constructor for the `corNatural` class, representing a general correlation structure in the “natural” parameterization, which is described under [pdNatural](#). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

## Usage

```
corNatural(value, form, fixed)
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code> | an optional vector with the parameter values. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).                                                                                                                                                                                                                                                                                                               |
| <code>form</code>  | a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| <code>fixed</code> | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                        |

## Value

covariate is observation order and grouping factor is Subject
cs1 <- corNatural(form = ~ 1 | Subject)
```

---

corRatio*Rational Quadratic Correlation Structure*

---

**Description**

This function is a constructor for the `corRatio` class, representing a rational quadratic spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $1/(1 + (r/d)^2)$  when no nugget effect is present and  $(1 - n)/(1 + (r/d)^2)$  when a nugget effect is assumed. Objects created using this constructor need to be later initialized using the appropriate `Initialize` method.

**Usage**

```
corRatio(value, form, nugget, metric, fixed)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code>  | an optional vector with the parameter values in constrained form. If <code>nugget</code> is FALSE, <code>value</code> can have only one element, corresponding to the "range" of the rational quadratic correlation structure, which must be greater than zero. If <code>nugget</code> is TRUE, meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| <code>form</code>   | a one sided formula of the form $\sim S1+\dots+Sp$ , or $\sim S1+\dots+Sp \mid g$ , specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.                                                                                                                                                                                                                                                                           |
| <code>nugget</code> | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>metric</code> | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>fixed</code>  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Value**

an object of class `corRatio`, also inheriting from class `corSpatial`, representing a rational quadratic spatial correlation structure.

**Description**

This function is a constructor for the *corSpatial* class, representing a spatial correlation structure. This class is "virtual", having four "real" classes, corresponding to specific spatial correlation structures, associated with it: *corExp*, *corGaus*, *corLin*, *corRatio*, and *corSpher*. The returned object will inherit from one of these "real" classes, determined by the *type* argument, and from the "virtual" *corSpatial* class. Objects created using this constructor must later be initialized using the appropriate *Initialize* method.

**Usage**

```
corSpatial(value, form, nugget, type, metric, fixed)
```

**Arguments**

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>value</b>  | an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the spatial correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| <b>form</b>   | a one sided formula of the form ~ S1+...+Sp, or ~ S1+...+Sp   g, specifying spatial covariates S1 through Sp and, optionally, a grouping factor g. When a grouping factor is present in form, the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to ~ 1, which corresponds to using the order of the observations in the data as a covariate, and no groups.                                                                                                                                                                                                                                            |
| <b>nugget</b> | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>type</b>   | an optional character string specifying the desired type of correlation structure. Available types include "spherical", "exponential", "gaussian", "linear", and "rational". See the documentation on the functions corSpher, corExp, corGaus, corLin, and corRatio for a description of these correlation structures. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "spherical".                                                                                                                                                                                                                                                                                                     |
| <b>metric</b> | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                                                                                                                                                                                                                     |
| <b>fixed</b>  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Value**

an object of class determined by the type argument and also inheriting from class corSpatial, representing a spatial correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

sp1 <- corSpatial(form = ~ x + y + z, type = "g", metric = "man")
```

**corSpher**

*Spherical Correlation Structure*

### Description

This function is a constructor for the **corSpher** class, representing a spherical spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r < d$  apart is  $1 - 1.5(r/d) + 0.5(r/d)^3$  when no nugget effect is present and  $(1 - n)(1 - 1.5(r/d) + 0.5(r/d)^3)$  when a nugget effect is assumed. If  $r \geq d$  the correlation is zero. Objects created using this constructor must later be initialized using the appropriate **Initialize** method.

### Usage

```
corSpher(value, form, nugget, metric, fixed)
```

### Arguments

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>value</b>  | an optional vector with the parameter values in constrained form. If nugget is FALSE, value can have only one element, corresponding to the "range" of the spherical correlation structure, which must be greater than zero. If nugget is TRUE, meaning that a nugget effect is present, value can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to numeric(0), which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized. |
| <b>form</b>   | a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <b>form</b> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.                                                                                                                                                                                              |
| <b>nugget</b> | an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|               |                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>metric</b> | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean". |
| <b>fixed</b>  | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.                                                                                                                                                                |

### Value

an object of class `corSpher`, also inheriting from class `corSpatial`, representing a spherical spatial correlation structure.

```

**corSymm***General Correlation Structure***Description**

This function is a constructor for the `corSymm` class, representing a general correlation structure. The internal representation of this structure, in terms of unconstrained parameters, uses the spherical parametrization defined in Pinheiro and Bates (1996). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corSymm(value, form, fixed)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code> | an optional vector with the parameter values. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate dimension being assigned to the parameters when object is initialized (corresponding to an identity correlation structure).                                                                                                                                                                                                                                                                                                            |
| <code>form</code>  | a one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups. |
| <code>fixed</code> | an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.                                                                                                                                                                                                                                                                                                                                     |

**Value**

an object of class `corSymm` representing a general correlation structure.

Pinheiro and Bates, pp. 261, 263
fm1Wheat2 <- gls(yield ~ variety - 1, Wheat2)
p. 262
fm2Wheat2 <- update(fm1Wheat2, corr =
 corSpher(c(28, 0.2),
 form = ~ latitude + longitude, nugget = TRUE))

example gls(..., corSymm ...)
Pinheiro and Bates, p. 251
fm1Orth.gls <- gls(distance ~ Sex * I(age - 11), Orthodont,
 correlation = corSymm(form = ~ 1 | Subject),
 weights = varIdent(form = ~ 1 | age))

```

## Covariate

## *Assign Covariate Values*

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all varFunc classes.

## Usage

```
covariate(object) <- value
```

## Arguments

- |        |                                                                 |
|--------|-----------------------------------------------------------------|
| object | any object with a covariate component.                          |
| value  | a value to be assigned to the covariate associated with object. |

## Value

will depend on the method function; see the appropriate documentation.

**Author(s)**

---

*Covariate.varFunc*      *Assign varFunc Covariate*

---

**Description**

The covariate(s) used in the calculation of the weights of the variance function represented by object is (are) replaced by value. If object has been initialized, value must have the same dimensions as `getCovariate(object)`.

**Usage**

```
S3 replacement method for class 'varFunc'
covariate(object) <- value
```

**Arguments**

|                     |                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>varFunc</code> , representing a variance function structure. |
| <code>value</code>  | a value to be assigned to the covariate associated with <code>object</code> .                      |

**Value**

a `varFunc` object similar to `object`, but with its `covariate` attribute replaced by `value`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[getCovariate.varFunc](#)

**Examples**

```
vf1 <- varPower(1.1, form = ~age)
covariate(vf1) <- Orthodont[["age"]]
```

|          |                               |
|----------|-------------------------------|
| Dialyzer | <i>High-Flux Hemodialyzer</i> |
|----------|-------------------------------|

---

**Description**

The Dialyzer data frame has 140 rows and 5 columns.

**Format**

This data frame contains the following columns:

**Subject** an ordered factor with levels 10 < 8 < 2 < 6 < 3 < 5 < 9 < 7 < 1 < 4 < 17 < 20 < 11 < 12 < 16 < 13 < 14 < 18 < 15 < 19 giving the unique identifier for each subject

**QB** a factor with levels 200 and 300 giving the bovine blood flow rate (dL/min).

**pressure** a numeric vector giving the transmembrane pressure (dmHg).

**rate** the hemodialyzer ultrafiltration rate (mL/hr).

**index** index of observation within subject—1 through 7.

**Details**

Vonesh and Carter (1992) describe data measured on high-flux hemodialyzers to assess their *in vivo* ultrafiltration characteristics. The ultrafiltration rates (in mL/hr) of 20 high-flux dialyzers were measured at seven different transmembrane pressures (in dmHg). The *in vitro* evaluation of the dialyzers used bovine blood at flow rates of either 200~dl/min or 300~dl/min. The data, are also analyzed in Littell, Milliken, Stroup, and Wolfinger (1996).

|-----|------------------------------------------|
| Dim | <i>Extract Dimensions from an Object</i> |
|-----|------------------------------------------|

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: corSpatial, corStruct, pdCompSymm, pdDiag, pdIdent, pdMat, and pdSymm.

**Usage**

```
Dim(object, ...)
```

**Arguments**

- object            any object for which dimensions can be extracted.
- ...                some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Note**

If `dim` allowed more than one argument, there would be no need for this generic function.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**See Also**

see the method function documentation
```

`Dim.corSpatial`

*Dimensions of a corSpatial Object*

**Description**

if `groups` is missing, it returns the `Dim` attribute of `object`; otherwise, calculates the dimensions associated with the grouping factor.

**Usage**

```
S3 method for class 'corSpatial'
Dim(object, groups, ...)
```

**Arguments**

- object            an object inheriting from class `corSpatial`, representing a spatial correlation structure.
- groups            an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.
- ...                further arguments to be passed to or from methods.

**Value**

a list with components:

|          |                                                                                                                                  |
|----------|----------------------------------------------------------------------------------------------------------------------------------|
| N        | length of groups                                                                                                                 |
| M        | number of groups                                                                                                                 |
| spClass  | an integer representing the spatial correlation class; 0 = user defined class, 1 = corSpher, 2 = corExp, 3 = corGaus, 4 = corLin |
| sumLenSq | sum of the squares of the number of observations per group                                                                       |
| len      | an integer vector with the number of observations per group                                                                      |
| start    | an integer vector with the starting position for the distance vectors in each group, beginning from zero                         |

Earthquake

*Earthquake Intensity*

---

## Description

The Earthquake data frame has 182 rows and 5 columns.

## Format

This data frame contains the following columns:

**Quake** an ordered factor with levels 20 < 16 < 14 < 10 < 3 < 8 < 23 < 22 < 6 < 13 < 7 < 21 < 18 < 15 < 4 < 12 < 19 < 5 < 9 < 1 < 2 < 17 < 11 indicating the earthquake on which the measurements were made.

**Richter** a numeric vector giving the intensity of the earthquake on the Richter scale.

**distance** the distance from the seismological measuring station to the epicenter of the earthquake (km).

**soil** a factor with levels 0 and 1 giving the soil condition at the measuring station, either soil or rock.

**accel** maximum horizontal acceleration observed (g).

## Details

Measurements recorded at available seismometer locations for 23 large earthquakes in western North America between 1940 and 1980. They were originally given in Joyner and Boore (1981); are mentioned in Brillinger (1987); and are analyzed in Davidian and Giltinan (1995).

**ergoStool***Ergometrics experiment with stool types*

---

### Description

The ergoStool data frame has 36 rows and 3 columns.

### Format

This data frame contains the following columns:

**effort** a numeric vector giving the effort (Borg scale) required to arise from a stool.

**Type** a factor with levels T1, T2, T3, and T4 giving the stool type.

**Subject** an ordered factor giving a unique identifier for the subject in the experiment.

### Details

Devore (2000) cites data from an article in *Ergometrics* (1993, pp. 519-535) on “The Effects of a Pneumatic Stool and a One-Legged Stool on Lower Limb Joint Load and Muscular Activity.”

---

**Fatigue***Cracks caused by metal fatigue*

---

### Description

The Fatigue data frame has 262 rows and 3 columns.

### Format

This data frame contains the following columns:

**Path** an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9 < 10 < 11 < 12 < 13 < 14 < 15 < 16 < 17 < 18 < 19 < 20 < 21 giving the test path (or test unit) number. The order is in terms of increasing failure time or decreasing terminal crack length.

**cycles** number of test cycles at which the measurement is made (millions of cycles).

**relLength** relative crack length (dimensionless).

## Details

These data are given in Lu and Meeker (1993) where they state “We obtained the data in Table 1 visually from figure 4.5.2 on page 242 of Bogdanoff and Kozin (1985).” The data represent the growth of cracks in metal for 21 test units. An initial notch of length 0.90 inches was made on each unit which then was subjected to several thousand test cycles. After every 10,000 test cycles the crack length was measured. Testing was stopped if the crack length exceeded 1.60 inches, defined as a failure, or at 120,000 cycles.

fdHess

*Finite difference Hessian*

## Description

Evaluate an approximate Hessian and gradient of a scalar function using finite differences.

## Usage

```
fdHess(pars, fun, ..., .relStep=.Machine$double.eps^(1/3), minAbsPar=0)
```

## Arguments

|                        |                                                                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pars</code>      | the numeric values of the parameters at which to evaluate the function <code>fun</code> and its derivatives.                                                        |
| <code>fun</code>       | a function depending on the parameters <code>pars</code> that returns a numeric scalar.                                                                             |
| <code>...</code>       | Optional additional arguments to <code>fun</code>                                                                                                                   |
| <code>.relStep</code>  | The relative step size to use in the finite differences. It defaults to the cube root of <code>.Machine\$double.eps</code>                                          |
| <code>minAbsPar</code> | The minimum magnitude of a parameter value that is considered non-zero. It defaults to zero meaning that any non-zero value will be considered different from zero. |

## Details

This function uses a second-order response surface design known as a Koschal design to determine the parameter values at which the function is evaluated.

## Value

A list with components

|                       |                                                                                            |
|-----------------------|--------------------------------------------------------------------------------------------|
| <code>mean</code>     | the value of function <code>fun</code> evaluated at the parameter values <code>pars</code> |
| <code>gradient</code> | an approximate gradient                                                                    |
| <code>Hessian</code>  | a matrix whose upper triangle contains an approximate Hessian.                             |

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
fdHess(c(12.3, 2.34), function(x) x[1]*(1-exp(-0.4*x[2])))
```

**fitted.glsStruct**

*Calculate glsStruct Fitted Values*

**Description**

The fitted values for the linear model represented by `object` are extracted.

**Usage**

```
S3 method for class 'glsStruct'
fitted(object, glsFit, ...)
```

**Arguments**

- |                     |                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.                                                                                                                                                                               |
| <code>glsFit</code> | an optional list with components <code>logLik</code> (log-likelihood), <code>beta</code> (coefficients), <code>sigma</code> (standard deviation for error term), <code>varBeta</code> (coefficients' covariance matrix), <code>fitted</code> (fitted values), and <code>residuals</code> (residuals). Defaults to <code>attr(object, "glsFit")</code> . |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                               |

**Value**

a vector with the fitted values for the linear model represented by `object`.

**Note**

This method function is generally only used inside `gls` and `fitted.gls`.

fitted.gnlsStruct      *Calculate gnlsStruct Fitted Values*

---

### Description

The fitted values for the nonlinear model represented by `object` are extracted.

### Usage

```
S3 method for class 'gnlsStruct'
fitted(object, ...)
```

### Arguments

- |                     |                                                                                                                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>gnlsStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects, and attributes specifying the underlying nonlinear model and the response variable. |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                               |

### Value

a vector with the fitted values for the nonlinear model represented by `object`.

### Note

This method function is generally only used inside `gnls` and `fitted.gnls`.

---

fitted.lme      *Extract lme Fitted Values*

---

### Description

The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ .

### Usage

```
S3 method for class 'lme'
fitted(object, level, asList, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                                                |
| <code>level</code>  | an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping. |
| <code>asList</code> | an optional logical value. If TRUE and a single value is given in <code>level</code> , the returned object is a list with the fitted values split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> . Defaults to FALSE.                         |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                           |

**Value**

If a single level of grouping is specified in `level`, the returned value is either a list with the fitted values split by groups (`asList` = TRUE) or a vector with the fitted values (`asList` = FALSE); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the fitted values at different levels and the grouping factors. For a vector or data frame result the `napredict` method is applied.

[fitted.lmList](#)

*Extract lmList Fitted Values*

**Description**

The fitted values are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

**Usage**

```
S3 method for class 'lmList'
fitted(object, subset, asList, ...)
```

**Arguments**

- object** an object inheriting from class `lmList`, representing a list of `lm` objects with a common model.
- subset** an optional character or integer vector naming the `lm` components of `object` from which the fitted values are to be extracted. Default is `NULL`, in which case all components are used.
- asList** an optional logical value. If `TRUE`, the returned object is a list with the fitted values split by groups; else the returned value is a vector. Defaults to `FALSE`.
- ...** some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with components given by the fitted values of each `lm` component of `object`, or a vector with the fitted values for all `lm` components of `object`.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

`fixed.effects`

*Extract Fixed Effects*

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmlist` and `lme`.

**Usage**

```
fixed.effects(object, ...)
fixef(object, ...)
```

**Arguments**

- object            any fitted model object from which fixed effects estimates can be extracted.
- ...                some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

[fixef.lmList](#)

**Examples**

```
see the method function documentation
```

**fixef.lmList**                  *Extract lmList Fixed Effects*

**Description**

The average of the coefficients corresponding to the `lm` components of `object` is calculated.

**Usage**

```
S3 method for class 'lmList'
fixef(object, ...)
```

**Arguments**

- object            an object inheriting from class `lmList`, representing a list of `lm` objects with a common model.
- ...                some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the average of the individual `lm` coefficients in `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|-------------------|----------------------------------|
| formula.pdBlocked | <i>Extract pdBlocked Formula</i> |
|-------------------|----------------------------------|

---

## Description

The formula attributes of the pdMat elements of x are extracted and returned as a list, in case asList=TRUE, or converted to a single one-sided formula when asList=FALSE. If the pdMat elements do not have a formula attribute, a NULL value is returned.

## Usage

```
S3 method for class 'pdBlocked'
formula(x, asList, ...)
```

## Arguments

- |        |                                                                                                                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | an object inheriting from class pdBlocked, representing a positive definite block diagonal matrix.                                                                                                                              |
| asList | an optional logical value. If TRUE, a list with the formulas for the individual block diagonal elements of x is returned; else, if FALSE, a one-sided formula combining all individual formulas is returned. Defaults to FALSE. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                       |

## Value

a list of one-sided formulas, or a single one-sided formula, or NULL.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

formula.pdMat      *Extract pdMat Formula*

---

## Description

This method function extracts the formula associated with a pdMat object, in which the column and row names are specified.

## Usage

```
S3 method for class 'pdMat'
formula(x, asList, ...)
```

## Arguments

|        |                                                                                              |
|--------|----------------------------------------------------------------------------------------------|
| x      | an object inheriting from class pdMat, representing a positive definite matrix.              |
| asList | logical. Should the asList argument be applied to each of the components?<br>Never used.     |
| ...    | some methods for this generic require additional arguments. None are used in<br>this method. |

## Value

if x has a formula attribute, its value is returned, else NULL is returned.

## Note

Because factors may be present in formula(x), the pdMat object needs to have access to a data frame where the variables named in the formula can be evaluated, before it can resolve its row and column names from the formula.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[pdMat](#)

## Examples

```
pd1 <- pdSymm(~Sex*age)
formula(pd1)
```

---

formula.reStruct      *Extract reStruct Object Formula*

---

## Description

This method function extracts a formula from each of the components of  $x$ , returning a list of formulas.

## Usage

```
S3 method for class 'reStruct'
formula(x, asList, ...)
```

## Arguments

$x$             an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of `pdMat` objects.  
 $asList$         logical. Should the `asList` argument be applied to each of the components?  
 $\dots$             some methods for this generic require additional arguments. None are used in this method.

## Value

a list with the formulas of each component of  $x$ .

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

## Examples

```
rs1 <- reStruct(list(A = pdDiag(diag(2), ~age), B = ~1))
formula(rs1)
```

---

gapply            *Apply a Function by Groups*

---

## Description

Applies the function to the distinct sets of rows of the data frame defined by `groups`.

## Usage

```
gapply(object, which, FUN, form, level, groups, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object to which the function will be applied - usually a groupedData object or a <code>data.frame</code> . Must inherit from class <code>data.frame</code> .                                                                                                                 |
| <code>which</code>  | an optional character or positive integer vector specifying which columns of <code>object</code> should be used with <code>FUN</code> . Defaults to all columns in <code>object</code> .                                                                                        |
| <code>FUN</code>    | function to apply to the distinct sets of rows of the data frame <code>object</code> defined by the values of groups.                                                                                                                                                           |
| <code>form</code>   | an optional one-sided formula that defines the groups. When this formula is given the right-hand side is evaluated in <code>object</code> , converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to <code>formula(object)</code> . |
| <code>level</code>  | an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.                                                                                                 |
| <code>groups</code> | an optional factor that will be used to split the rows into groups. Defaults to <code>getGroups(object, form, level)</code> .                                                                                                                                                   |
| <code>...</code>    | optional additional arguments to the summary function <code>FUN</code> . Often it is helpful to specify <code>na.rm = TRUE</code> .                                                                                                                                             |

**Value**

Returns a data frame with as many rows as there are levels in the `groups` argument.

Pinheiro and Bates, p. 127
table(gapply(Quinidine, "conc", function(x) sum(!is.na(x))))
changeRecords <- gapply(Quinidine, FUN = function(frm)
 any(is.na(frm[["conc"]]) & is.na(frm[["dose"]])))
```

---

|          |                                   |
|----------|-----------------------------------|
| Gasoline | <i>Refinery yield of gasoline</i> |
|----------|-----------------------------------|

---

## Description

The Gasoline data frame has 32 rows and 6 columns.

## Format

This data frame contains the following columns:

- yield** a numeric vector giving the percentage of crude oil converted to gasoline after distillation and fractionation
- endpoint** a numeric vector giving the temperature (degrees F) at which all the gasoline is vaporized
- Sample** an ordered factor giving the inferred crude oil sample number
- API** a numeric vector giving the crude oil gravity (degrees API)
- vapor** a numeric vector giving the vapor pressure of the crude oil ( $\text{lbf/in}^2$ )
- ASTM** a numeric vector giving the crude oil 10% point ASTM—the temperature at which 10% of the crude oil has become vapor.

## Details

Prater (1955) provides data on crude oil properties and gasoline yields. Atkinson (1985) uses these data to illustrate the use of diagnostics in multiple regression analysis. Three of the covariates—API, vapor, and ASTM—measure characteristics of the crude oil used to produce the gasoline. The other covariate — endpoint—is a characteristic of the refining process. Daniel and Wood (1980) notice that the covariates characterizing the crude oil occur in only ten distinct groups and conclude that the data represent responses measured on ten different crude oil samples.

|--------------|-----------------------------------------|
| getCovariate | <i>Extract Covariate from an Object</i> |
|--------------|-----------------------------------------|

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `corStruct`, `corSpatial`, `data.frame`, and `varFunc`.

**Usage**

```
getCovariate(object, form, data)
```

**Arguments**

|        |                                                                                                                       |
|--------|-----------------------------------------------------------------------------------------------------------------------|
| object | any object with a covariate component                                                                                 |
| form   | an optional one-sided formula specifying the covariate(s) to be extracted. Defaults to <code>formula(object)</code> . |
| data   | a data frame in which to evaluate the variables defined in <code>form</code> .                                        |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

`getCovariateFormula`

**Examples**

```
see the method function documentation
```

`getCovariate.corStruct`

*Extract corStruct Object Covariate*

**Description**

This method function extracts the covariate(s) associated with `object`.

**Usage**

```
S3 method for class 'corStruct'
getCovariate(object, form, data)
```

**Arguments**

|        |                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>corStruct</code> representing a correlation structure.                                                                                     |
| form   | this argument is included to make the method function compatible with the generic. It will be assigned the value of <code>formula(object)</code> and should not be modified.     |
| data   | an optional data frame in which to evaluate the variables defined in <code>form</code> , in case <code>object</code> is not initialized and the covariate needs to be evaluated. |

**Value**

when the correlation structure does not include a grouping factor, the returned value will be a vector or a matrix with the covariate(s) associated with `object`. If a grouping factor is present, the returned value will be a list of vectors or matrices with the covariate(s) corresponding to each grouping level.

getCovariate(cs1, data = Orthodont)
```

---

getCovariate.data.frame  
*Extract Data Frame Covariate*

---

**Description**

The right hand side of `form`, stripped of any conditioning expression (i.e. an expression following a `|` operator), is evaluated in `object`.

**Usage**

```
S3 method for class 'data.frame'
getCovariate(object, form, data)
```

**Arguments**

- |                     |                                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>data.frame</code> .                                                                        |
| <code>form</code>   | an optional formula specifying the covariate to be evaluated in <code>object</code> . Defaults to <code>formula(object)</code> . |
| <code>data</code>   | some methods for this generic require a separate data frame. Not used in this method.                                            |

**Value**

the value of the right hand side of `form`, stripped of any conditional expression, evaluated in `object`.

[getCovariateFormula](#)

**Examples**

```
getCovariate(Orthodont)
```

`getCovariate.varFunc`    *Extract varFunc Covariate*

**Description**

This method function extracts the covariate(s) associated with the variance function represented by `object`, if any is present.

**Usage**

```
S3 method for class 'varFunc'
getCovariate(object, form, data)
```

**Arguments**

- |                     |                                                                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>varFunc</code> , representing a variance function structure.                               |
| <code>form</code>   | an optional formula specifying the covariate to be evaluated in <code>object</code> . Defaults to <code>formula(object)</code> . |
| <code>data</code>   | some methods for this generic require a <code>data</code> object. Not used in this method.                                       |

**Value**

if `object` has a `covariate` attribute, its value is returned; else `NULL` is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

vf1 <- varPower(1.1, form = ~age)
covariate(vf1) <- Orthodont[["age"]]
getCovariate(vf1)
```

---

getCovariateFormula     *Extract Covariates Formula*

---

## Description

The right hand side of `formula(object)`, without any conditioning expressions (i.e. any expressions after a `|` operator) is returned as a one-sided formula.

## Usage

`getCovariateFormula(object)`

## Arguments

`object`        any object from which a formula can be extracted.

## Value

a one-sided formula describing the covariates associated with `formula(object)`.

## Author(s)

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

## See Also

[getCovariate](#)

## Examples

```
getCovariateFormula(y ~ x | g)
getCovariateFormula(y ~ x)
```

---

getData                  *Extract Data from an Object*

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `gls`, `lme`, and `lmList`.

## Usage

`getData(object)`

## Arguments

`object`        an object from which a `data.frame` can be extracted, generally a fitted model object.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[getData.gls](#), [getData.lme](#), [getData.lmList](#)

**Examples**

```
see the method function documentation
```

**getData.gls**

*Extract gls Object Data*

**Description**

If present in the calling sequence used to produce `object`, the data frame used to fit the model is obtained.

**Usage**

```
S3 method for class 'gls'
getData(object)
```

**Arguments**

|                     |                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model. |
|---------------------|------------------------------------------------------------------------------------------------------------------|

**Value**

if a `data` argument is present in the calling sequence that produced `object`, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced `object`) is returned; else, `NULL` is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gls](#), [getData](#)

**Examples**

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,
 correlation = corAR1(form = ~ 1 | Mare))
getData(fm1)
```

---

getData.lme                  *Extract lme Object Data*

---

## Description

If present in the calling sequence used to produce object, the data frame used to fit the model is obtained.

## Usage

```
S3 method for class 'lme'
getData(object)
```

## Arguments

object                  an object inheriting from class `lme`, representing a linear mixed-effects fitted model.

## Value

if a `data` argument is present in the calling sequence that produced `object`, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced `object`) is returned; else, `NULL` is returned.

Note that as from version 3.1-102, this only omits rows omitted in the fit if `na.action = na.omit`, and does not omit at all if `na.action = na.exclude`. That is generally what is wanted for plotting, the main use of this function.

## Author(s)

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

## See Also

fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,
 random = ~ sin(2*pi*Time))
getData(fm1)
```

`getData.lmList`      *Extract lmList Object Data*

### Description

If present in the calling sequence used to produce `object`, the data frame used to fit the model is obtained.

### Usage

```
S3 method for class 'lmList'
getData(object)
```

### Arguments

|                     |                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model. |
|---------------------|---------------------------------------------------------------------------------------------------------------------------|

### Value

if a `data` argument is present in the calling sequence that produced `object`, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced `object`) is returned; else, `NULL` is returned.

### Author(s)

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

### See Also

fm1 <- lmList(distance ~ age | Subject, Orthodont)
getData(fm1)
```

`getGroups`      *Extract Grouping Factors from an Object*

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `corStruct`, `data.frame`, `gls`, `lme`, `lmList`, and `varFunc`.

### Usage

```
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |                                                                                                                                                                                                                                    |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | any object                                                                                                                                                                                                                         |
| form   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the   operator). Defaults to formula(object).                                                                              |
| level  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. |
| data   | a data frame in which to interpret the variables named in form. Optional for most methods.                                                                                                                                         |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is '/'.                                                                                                                       |

**Value**

will depend on the method function used; see the appropriate documentation.

```

---

getGroups.corStruct    *Extract corStruct Groups*

---

**Description**

This method function extracts the grouping factor associated with object, if any is present.

**Usage**

```
S3 method for class 'corStruct'
getGroups(object, form, level, data, sep)
```

**Arguments**

|                     |                                                                                                                                                                                        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>corStruct</code> representing a correlation structure.                                                                                           |
| <code>form</code>   | this argument is included to make the method function compatible with the generic. It will be assigned the value of <code>formula(object)</code> and should not be modified.           |
| <code>level</code>  | this argument is included to make the method function compatible with the generic and is not used.                                                                                     |
| <code>data</code>   | an optional data frame in which to evaluate the variables defined in <code>form</code> , in case <code>object</code> is not initialized and the grouping factor needs to be evaluated. |
| <code>sep</code>    | character, the separator to use between group levels when multiple levels are collapsed. The default is '/'.                                                                           |

**Value**

if a grouping factor is present in the correlation structure represented by `object`, the function returns the corresponding factor vector; else the function returns `NULL`.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**See Also**

[getGroups](#)

**Examples**

```
cs1 <- corAR1(form = ~ 1 | Subject)
getGroups(cs1, data = Orthodont)
```

`getGroups.data.frame`    *Extract Groups from a Data Frame*

**Description**

Each variable named in the expression after the `|` operator on the right hand side of `form` is evaluated in `object`. If more than one variable is indicated in `level` they are combined into a data frame; else the selected variable is returned as a vector. When multiple grouping levels are defined in `form` and `level > 1`, the levels of the returned factor are obtained by pasting together the levels of the grouping factors of level greater or equal to `level`, to ensure their uniqueness.

**Usage**

```
S3 method for class 'data.frame'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>data.frame</code> .                                                                                                                        |
| form   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . |
| level  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. Defaults to all levels of nesting.                       |
| data   | unused                                                                                                                                                                           |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .                                                       |

**Value**

either a data frame with columns given by the grouping factors indicated in `level`, from outer to inner, or, when a single level is requested, a factor representing the selected grouping factor.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```
getGroups(Pixel)
getGroups(Pixel, level = 2)
```

---

`getGroups.gls`      *Extract gls Object Groups*

---

**Description**

If present, the grouping factor associated to the correlation structure for the linear model represented by `object` is extracted.

**Usage**

```
S3 method for class 'gls'
getGroups(object, form, level, data, sep)
```

**Arguments**

|               |                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b> | an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model.                                                                                                                             |
| <b>form</b>   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . Not used.                                                   |
| <b>level</b>  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used. |
| <b>data</b>   | a data frame in which to interpret the variables named in <code>form</code> . Optional for most methods. Not used.                                                                                                                           |
| <b>sep</b>    | character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> . Not used.                                                                                                         |

**Value**

if the linear model represented by `object` incorporates a correlation structure and the corresponding `corStruct` object has a grouping factor, a vector with the group values is returned; else, `NULL` is returned.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**See Also**

**Examples**

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
 correlation = corAR1(form = ~ 1 | Mare))
getGroups(fm1)
```

*getGroups.lme*

*Extract lme Object Groups*

**Description**

The grouping factors corresponding to the linear mixed-effects model represented by `object` are extracted. If more than one level is indicated in `level`, the corresponding grouping factors are combined into a data frame; else the selected grouping factor is returned as a vector.

**Usage**

```
S3 method for class 'lme'
getGroups(object, form, level, data, sep)
```

### Arguments

|        |                                                                                                                                                               |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                          |
| form   | this argument is included to make the method function compatible with the generic and is ignored in this method.                                              |
| level  | an optional integer vector giving the level(s) of grouping to be extracted from <code>object</code> . Defaults to the highest or innermost level of grouping. |
| data   | unused                                                                                                                                                        |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is '/'.                                                  |

### Value

either a data frame with columns given by the grouping factors indicated in `level`, or, when a single level is requested, a factor representing the selected grouping factor.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

### Examples

```
fm1 <- lme(pixel ~ day + day^2, Pixel,
 random = list(Dog = ~day, Side = ~1))
getGroups(fm1, level = 1:2)
```

`getGroups.lmList`      *Extract lmList Object Groups*

### Description

The grouping factor determining the partitioning of the observations used to produce the `lme` components of `object` is extracted.

### Usage

```
S3 method for class 'lmList'
getGroups(object, form, level, data, sep)
```

**Arguments**

|               |                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b> | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.                                                                                                                    |
| <b>form</b>   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . Not used.                                                   |
| <b>level</b>  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used. |
| <b>data</b>   | a data frame in which to interpret the variables named in <code>form</code> . Optional for most methods. Not used.                                                                                                                           |
| <b>sep</b>    | character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> . Not used.                                                                                                         |

**Value**

a vector with the grouping factor corresponding to the `lm` components of `object`.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**See Also**

`getGroups.varFunc`      *Extract varFunc Groups*

**Description**

This method function extracts the grouping factor associated with the variance function represented by `object`, if any is present.

**Usage**

```
S3 method for class 'varFunc'
getGroups(object, form, level, data, sep)
```

**Arguments**

|        |                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class varFunc, representing a variance function structure.                                                                                                                                                         |
| form   | an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the   operator). Defaults to formula(object). Not used.                                                                              |
| level  | a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used. |
| data   | a data frame in which to interpret the variables named in form. Optional for most methods. Not used.                                                                                                                                         |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is '/'. Not used.                                                                                                                       |

**Value**

if object has a groups attribute, its value is returned; else NULL is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
vf1 <- varPower(form = ~ age | Sex)
vf1 <- Initialize(vf1, Orthodont)
getGroups(vf1)
```

**Description**

The conditioning expression associated with formula(object) (i.e. the expression after the | operator) is returned either as a named list of one-sided formulas, or a single one-sided formula, depending on the value of asList. The components of the returned list are ordered from outermost to innermost level and are named after the grouping factor expression.

**Usage**

```
getGroupsFormula(object, asList, sep)
```

**Arguments**

|        |                                                                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | any object from which a formula can be extracted.                                                                                                                   |
| asList | an optional logical value. If TRUE the returned value will be a list of formulas; else, if FALSE the returned value will be a one-sided formula. Defaults to FALSE. |
| sep    | character, the separator to use between group levels when multiple levels are collapsed. The default is '/'.                                                        |

**Value**

a one-sided formula, or a list of one-sided formulas, with the grouping structure associated with `formula(object)`. If no conditioning expression is present in `formula(object)` a NULL value is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

`getResponse`

*Extract Response Variable from an Object*

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `data.frame`, `gls`, `lme`, and `lmList`.

**Usage**

```
getResponse(object, form)
```

**Arguments**

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| <code>object</code> | any object                                                                |
| <code>form</code>   | an optional two-sided formula. Defaults to <code>formula(object)</code> . |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[getResponseFormula](#)

**Examples**

```
getResponse(Orthodont)
```

---

getResponseFormula      *Extract Formula Specifying Response Variable*

---

## Description

The left hand side of `formula{object}` is returned as a one-sided formula.

## Usage

`getResponseFormula(object)`

## Arguments

`object`      any object from which a formula can be extracted.

## Value

a one-sided formula with the response variable associated with `formula{object}`.

## Author(s)

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

## See Also

## Examples

`getResponseFormula(y ~ x | g)`

---

getVarCov      *Extract variance-covariance matrix*

---

## Description

Extract the variance-covariance matrix from a fitted model, such as a mixed-effects model.

## Usage

```
getVarCov(obj, ...)
S3 method for class 'lme'
getVarCov(obj, individuals,
 type = c("random.effects", "conditional", "marginal"), ...)
S3 method for class 'gls'
getVarCov(obj, individual = 1, ...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>obj</code>         | A fitted model. Methods are available for models fit by <a href="#">lme</a> and by <a href="#">gls</a>                                                                                                                                                                                                                                         |
| <code>individuals</code> | For models fit by <a href="#">lme</a> a vector of levels of the grouping factor can be specified for the conditional or marginal variance-covariance matrices.                                                                                                                                                                                 |
| <code>individual</code>  | For models fit by <a href="#">gls</a> the only type of variance-covariance matrix provided is the marginal variance-covariance of the responses by group. The optional argument <code>individual</code> specifies the group of responses.                                                                                                      |
| <code>type</code>        | For models fit by <a href="#">lme</a> the type argument specifies the type of variance-covariance matrix, either "random.effects" for the random-effects variance-covariance (the default), or "conditional" for the conditional variance-covariance of the responses or "marginal" for the the marginal variance-covariance of the responses. |
| ...                      | Optional arguments for some methods, as described above                                                                                                                                                                                                                                                                                        |

**Value**

A variance-covariance matrix or a list of variance-covariance matrices.

**Author(s)**

Mary Lindstrom <lindstro@biostat.wisc.edu>

**See Also**

**Examples**

```
fm1 <- lme(distance ~ age, data = Orthodont, subset = Sex == "Female")
getVarCov(fm1)
getVarCov(fm1, individual = "F01", type = "marginal")
getVarCov(fm1, type = "conditional")
fm2 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
 correlation = corAR1(form = ~ 1 | Mare))
getVarCov(fm2)
```

**gls**

*Fit Linear Model Using Generalized Least Squares*

**Description**

This function fits a linear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
gls(model, data, correlation, weights, subset, method, na.action,
 control, verbose)
S3 method for class 'gls'
update(object, model., ..., evaluate = TRUE)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b>      | an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model.                                                                                                                                                                                                                                                                                                                      |
| <b>model</b>       | a two-sided linear formula object describing the model, with the response on the left of a <code>~</code> operator and the terms, separated by <code>+</code> operators, on the right.                                                                                                                                                                                                                                                |
| <b>model.</b>      | Changes to the model – see <code>update.formula</code> for details.                                                                                                                                                                                                                                                                                                                                                                   |
| <b>data</b>        | an optional data frame containing the variables named in <code>model</code> , <code>correlation</code> , <code>weights</code> , and <code>subset</code> . By default the variables are taken from the environment from which <code>gls</code> is called.                                                                                                                                                                              |
| <b>correlation</b> | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. If a grouping variable is to be used, it must be specified in the <code>form</code> argument to the <code>corStruct</code> constructor. Defaults to <code>NULL</code> , corresponding to uncorrelated errors.        |
| <b>weights</b>     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic errors. |
| <b>subset</b>      | an optional expression indicating which subset of the rows of <code>data</code> should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                |
| <b>method</b>      | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".                                                                                                                                                                                                                                                                              |
| <b>na.action</b>   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>gls</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                         |
| <b>control</b>     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>glsControl</code> . Defaults to an empty list.                                                                                                                                                                                                                                                                     |
| <b>verbose</b>     | an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.                                                                                                                                                                                                                                                                                                              |
| <b>...</b>         | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                             |
| <b>evaluate</b>    | If TRUE evaluate the new call else return the call.                                                                                                                                                                                                                                                                                                                                                                                   |

**Value**

an object of class `gls` representing the linear model fit. Generic functions such as `print`, `plot`, and `summary` have methods to show the results of the fit. See `glsObject` for the components of the fit. The functions `resid`, `coef`, and `fitted` can be used to extract some of its components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

The different correlation structures available for the correlation argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littel, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). The use of variance functions for linear and nonlinear models is presented in detail in Carroll, R.J. and Ruppert, D. (1988) and Davidian, M. and Giltinan, D.M. (1995).

## Examples

```
AR(1) errors within each Mare
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
 correlation = corAR1(form = ~ 1 | Mare))
variance increases as a power of the absolute fitted values
fm2 <- update(fm1, weights = varPower())
```

## Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the `gls` function.

## Usage

```
glsControl(maxIter, msMaxIter, tolerance, msTol, msScale, msVerbose,
 singular.ok, qrTol, returnObject, apVar, .relStep,
 nlmStepMax, opt=c("nlminb", "optim"), optimMethod,
 minAbsParApVar, natural)
```

### Arguments

|                |                                                                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maxIter        | maximum number of iterations for the gls optimization algorithm. Default is 50.                                                                                                    |
| msMaxIter      | maximum number of iterations for the optimization step inside the gls optimization. Default is 50.                                                                                 |
| tolerance      | tolerance for the convergence criterion in the gls algorithm. Default is 1e-6.                                                                                                     |
| msTol          | tolerance for the convergence criterion in ms, passed as the rel.tolerance argument to the function (see documentation on ms). Default is 1e-7.                                    |
| msScale        | scale function passed as the scale argument to the ms function (see documentation on that function). Default is lmeScale.                                                          |
| msVerbose      | a logical value passed as the trace argument to ms (see documentation on that function). Default is FALSE.                                                                         |
| singular.ok    | a logical value indicating whether non-estimable coefficients (resulting from linear dependencies among the columns of the regression matrix) should be allowed. Default is FALSE. |
| qrTol          | a tolerance for detecting linear dependencies among the columns of the regression matrix in its QR decomposition. Default is .Machine\$single.eps.                                 |
| returnObject   | a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.   |
| apVar          | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.                                  |
| .relStep       | relative step for numerical derivatives calculations. Default is .Machine\$double.eps^(1/3).                                                                                       |
| nlmStepMax     | stepmax value to be passed to nlm. See <a href="#">nlm</a> for details. Default is 100.0                                                                                           |
| opt            | the optimizer to be used, either <a href="#">nlinb</a> (the default since (R 2.2.0) or <a href="#">optim</a> (the previous default).                                               |
| optimMethod    | character - the optimization method to be used with the <a href="#">optim</a> optimizer. The default is "BFGS". An alternative is "L-BFGS-B".                                      |
| minAbsParApVar | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.                                                                     |
| natural        | logical. Should the natural parameterization be used for the approximate variance calculations? Default is TRUE.                                                                   |

### Value

a list with components for each of the possible arguments.

## Examples

```
decrease the maximum number iterations in the optimization call and
request that information on the evolution of the ms iterations be printed
glsControl(msMaxIter = 20, msVerbose = TRUE)
```

*glsObject*

*Fitted gls Object*

## Description

An object returned by the `gls` function, inheriting from class `gls` and representing a generalized least squares fitted linear model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

## Value

The following components must be included in a legitimate `gls` object.

|                           |                                                                                                                                                                                                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>apVar</code>        | an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>gls</code> , this component is equal to <code>NULL</code> .                                                                  |
| <code>call</code>         | a list containing an image of the <code>gls</code> call that produced the object.                                                                                                                                                                                                             |
| <code>coefficients</code> | a vector with the estimated linear model coefficients.                                                                                                                                                                                                                                        |
| <code>contrasts</code>    | a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list. |
| <code>dims</code>         | a list with basic dimensions used in the model fit, including the components <code>N</code> - the number of observations in the data and <code>p</code> - the number of coefficients in the linear model.                                                                                     |
| <code>fitted</code>       | a vector with the fitted values..                                                                                                                                                                                                                                                             |
| <code>glsStruct</code>    | an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.                                                                                                                     |
| <code>groups</code>       | a vector with the correlation structure grouping factor, if any is present.                                                                                                                                                                                                                   |
| <code>logLik</code>       | the log-likelihood at convergence.                                                                                                                                                                                                                                                            |
| <code>method</code>       | the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.                                                                                                                                                                                       |
| <code>numIter</code>      | the number of iterations used in the iterative algorithm.                                                                                                                                                                                                                                     |
| <code>residuals</code>    | a vector with the residuals.                                                                                                                                                                                                                                                                  |
| <code>sigma</code>        | the estimated residual standard error.                                                                                                                                                                                                                                                        |
| <code>varBeta</code>      | an approximate covariance matrix of the coefficients estimates.                                                                                                                                                                                                                               |

**glsStruct***Generalized Least Squares Structure*

---

**Description**

A generalized least squares structure is a list of model components representing different sets of parameters in the linear model. A glsStruct may contain corStruct and varFunc objects. NULL arguments are not included in the glsStruct list.

**Usage**

```
glsStruct(corStruct, varStruct)
```

**Arguments**

- |           |                                                                                          |
|-----------|------------------------------------------------------------------------------------------|
| corStruct | an optional corStruct object, representing a correlation structure. Default is NULL.     |
| varStruct | an optional varFunc object, representing a variance function structure. Default is NULL. |

**Value**

a list of model variance-covariance components determining the parameters to be estimated for the associated linear model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**[corClasses](#), [gls](#), [residuals.glsStruct](#), [varFunc](#)**Examples**

```
gls1 <- glsStruct(corAR1(), varPower())
```

|---------|---------------------------------|
| Glucose | <i>Glucose levels over time</i> |
|---------|---------------------------------|

---

### Description

The Glucose data frame has 378 rows and 4 columns.

### Format

This data frame contains the following columns:

**Subject** an ordered factor with levels 6 < 2 < 3 < 5 < 1 < 4

**Time** a numeric vector

**conc** a numeric vector of glucose levels

**Meal** an ordered factor with levels 2am < 6am < 10am < 2pm < 6pm < 10pm

|          |                                                   |
|----------|---------------------------------------------------|
| Glucose2 | <i>Glucose Levels Following Alcohol Ingestion</i> |
|----------|---------------------------------------------------|

---

### Description

The Glucose2 data frame has 196 rows and 4 columns.

### Format

This data frame contains the following columns:

**Subject** a factor with levels 1 to 7 identifying the subject whose glucose level is measured.

**Date** a factor with levels 1 2 indicating the occasion in which the experiment was conducted.

**Time** a numeric vector giving the time since alcohol ingestion (in min/10).

**glucose** a numeric vector giving the blood glucose level (in mg/dl).

### Details

Hand and Crowder (Table A.14, pp. 180-181, 1996) describe data on the blood glucose levels measured at 14 time points over 5 hours for 7 volunteers who took alcohol at time 0. The same experiment was repeated on a second date with the same subjects but with a dietary additive used for all subjects.

**gnls***Fit Nonlinear Model Using Generalized Least Squares*

---

**Description**

This function fits a nonlinear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
gnls(model, data, params, start, correlation, weights, subset,
 na.action, naPattern, control, verbose)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>model</b>       | a two-sided formula object describing the model, with the response on the left of a $\sim$ operator and a nonlinear expression involving parameters and covariates on the right. If <b>data</b> is given, all names used in the formula should be defined as parameters or variables in the data frame.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>data</b>        | an optional data frame containing the variables named in <b>model</b> , <b>correlation</b> , <b>weights</b> , <b>subset</b> , and <b>naPattern</b> . By default the variables are taken from the environment from which <b>gnls</b> is called.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>params</b>      | an optional two-sided linear formula of the form $p_1 + \dots + p_n \sim x_1 + \dots + x_m$ , or list of two-sided formulas of the form $p_1 \sim x_1 + \dots + x_m$ , with possibly different models for each parameter. The $p_1, \dots, p_n$ represent parameters included on the right hand side of <b>model</b> and $x_1 + \dots + x_m$ define a linear model for the parameters (when the left hand side of the formula contains several parameters, they are all assumed to follow the same linear model described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s). By default, the parameters are obtained from the names of <b>start</b> . |
| <b>start</b>       | an optional named list, or numeric vector, with the initial values for the parameters in <b>model</b> . It can be omitted when a <b>selfStarting</b> function is used in <b>model</b> , in which case the starting estimates will be obtained from a single call to the <b>nls</b> function.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>correlation</b> | an optional <b>corStruct</b> object describing the within-group correlation structure. See the documentation of <b>corClasses</b> for a description of the available <b>corStruct</b> classes. If a grouping variable is to be used, it must be specified in the <b>form</b> argument to the <b>corStruct</b> constructor. Defaults to <b>NULL</b> , corresponding to uncorrelated errors.                                                                                                                                                                                                                                                                                                                                                               |
| <b>weights</b>     | an optional <b>varFunc</b> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <b>varFixed</b> , corresponding to fixed variance weights. See the documentation on <b>varClasses</b> for a description of the available <b>varFunc</b> classes. Defaults to <b>NULL</b> , corresponding to homoscedastic errors.                                                                                                                                                                                                                                                                                                                                                  |

|           |                                                                                                                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| subset    | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| na.action | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>gnls</code> to print an error message and terminate if there are any incomplete observations.                                                                            |
| naPattern | an expression or formula object, specifying which returned values are to be regarded as missing.                                                                                                                                                                                                          |
| control   | a list of control values for the estimation algorithm to replace the default values returned by the function <code>gnlsControl</code> . Defaults to an empty list.                                                                                                                                        |
| verbose   | an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.                                                                                                                                                                                  |
| ...       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                 |

### Value

an object of class `gnls`, also inheriting from class `gls`, representing the nonlinear model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `gnlsObject` for the components of the fit. The functions `resid`, `coef`, and `fitted` can be used to extract some of its components.

## Examples

```
variance increases with a power of the absolute fitted values
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
 weights = varPower())
summary(fm1)
```

### gnlsControl

### *Control Values for gnls Fit*

## Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `gnls` function.

## Usage

```
gnlsControl(maxIter, nlsMaxIter, msMaxIter, minScale, tolerance,
 nlsTol, msTol, msScale, returnObject, msVerbose,
 apVar, .relStep, nlmStepMax,
 opt = c("nlminb", "optim"), optimMethod,
 minAbsParApVar)
```

## Arguments

|                           |                                                                                                                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>maxIter</code>      | maximum number of iterations for the <code>gnls</code> optimization algorithm. Default is 50.                                                                                            |
| <code>nlsMaxIter</code>   | maximum number of iterations for the <code>nls</code> optimization step inside the <code>gnls</code> optimization. Default is 7.                                                         |
| <code>msMaxIter</code>    | maximum number of iterations for the <code>ms</code> optimization step inside the <code>gnls</code> optimization. Default is 50.                                                         |
| <code>minScale</code>     | minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the <code>nls</code> step. Default 0.001.                                        |
| <code>tolerance</code>    | tolerance for the convergence criterion in the <code>gnls</code> algorithm. Default is 1e-6.                                                                                             |
| <code>nlsTol</code>       | tolerance for the convergence criterion in <code>nls</code> step. Default is 1e-3.                                                                                                       |
| <code>msTol</code>        | tolerance for the convergence criterion in <code>ms</code> , passed as the <code>rel.tolerance</code> argument to the function (see documentation on <code>ms</code> ). Default is 1e-7. |
| <code>msScale</code>      | scale function passed as the <code>scale</code> argument to the <code>ms</code> function (see documentation on that function). Default is <code>lmeScale</code> .                        |
| <code>returnObject</code> | a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.         |
| <code>msVerbose</code>    | a logical value passed as the <code>trace</code> argument to <code>ms</code> (see documentation on that function). Default is FALSE.                                                     |
| <code>apVar</code>        | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.                                        |
| <code>.relStep</code>     | relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .                                                                               |

|                             |                                                                                                                                            |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>opt</code>            | the optimizer to be used, either <code>n1mnb</code> (the default since (R 2.2.0) or <code>optim</code> (the previous default).             |
| <code>optimMethod</code>    | character - the optimization method to be used with the <code>optim</code> optimizer. The default is "BFGS". An alternative is "L-BFGS-B". |
| <code>n1mStepMax</code>     | stepmax value to be passed to nlm. See <code>nlm</code> for details. Default is 100.0                                                      |
| <code>minAbsParApVar</code> | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.                             |

**Value**

a list with components for each of the possible arguments.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`gnls`, `lmeScale`

**Examples**

```
decrease the maximum number iterations in the ms call and
request that information on the evolution of the ms iterations be printed
gnlsControl(msMaxIter = 20, msVerbose = TRUE)
```

*gnlsObject*

*Fitted gnls Object*

**Description**

An object returned by the `gnls` function, inheriting from class `gnls` and also from class `gls`, and representing a generalized nonlinear least squares fitted model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate `gnls` object.

|                           |                                                                                                                                                                                                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>apVar</code>        | an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>gnls</code> , this component is equal to NULL.                                                                               |
| <code>call</code>         | a list containing an image of the <code>gnls</code> call that produced the object.                                                                                                                                                                                                            |
| <code>coefficients</code> | a vector with the estimated nonlinear model coefficients.                                                                                                                                                                                                                                     |
| <code>contrasts</code>    | a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list. |

|             |                                                                                                                                                                                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dims        | a list with basic dimensions used in the model fit, including the components N - the number of observations used in the fit and p - the number of coefficients in the nonlinear model. |
| fitted      | a vector with the fitted values.                                                                                                                                                       |
| modelStruct | an object inheriting from class <code>gnlsStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects.                    |
| groups      | a vector with the correlation structure grouping factor, if any is present.                                                                                                            |
| logLik      | the log-likelihood at convergence.                                                                                                                                                     |
| numIter     | the number of iterations used in the iterative algorithm.                                                                                                                              |
| plist       |                                                                                                                                                                                        |
| pmap        |                                                                                                                                                                                        |
| residuals   | a vector with the residuals.                                                                                                                                                           |
| sigma       | the estimated residual standard error.                                                                                                                                                 |
| varBeta     | an approximate covariance matrix of the coefficients estimates.                                                                                                                        |

`gnlsStruct`

*Generalized Nonlinear Least Squares Structure*

---

### Description

A generalized nonlinear least squares structure is a list of model components representing different sets of parameters in the nonlinear model. A `gnlsStruct` may contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `gnlsStruct` list.

### Usage

```
gnlsStruct(corStruct, varStruct)
```

### Arguments

|                        |                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>corStruct</code> | an optional <code>corStruct</code> object, representing a correlation structure. Default is <code>NULL</code> .     |
| <code>varStruct</code> | an optional <code>varFunc</code> object, representing a variance function structure. Default is <code>NULL</code> . |

### Value

a list of model variance-covariance components determining the parameters to be estimated for the associated nonlinear model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
gnls1 <- gnlsStruct(corAR1(), varPower())
```

**groupedData**

*Construct a groupedData Object*

**Description**

An object of the *groupedData* class is constructed from the *formula* and *data* by attaching the *formula* as an attribute of the data, along with any of *outer*, *inner*, *labels*, and *units* that are given. If *order.groups* is TRUE the grouping factor is converted to an ordered factor with the ordering determined by *FUN*. Depending on the number of grouping levels and the type of primary covariate, the returned object will be of one of three classes: *nfnGroupedData* - numeric covariate, single level of nesting; *nffGroupedData* - factor covariate, single level of nesting; and *nmGroupedData* - multiple levels of nesting. Several modeling and plotting functions can use the formula stored with a *groupedData* object to construct default plots and models.

**Usage**

```
groupedData(formula, data, order.groups, FUN, outer, inner,
 labels, units)
S3 method for class 'groupedData'
update(object, formula, data, order.groups, FUN,
 outer, inner, labels, units, ...)
```

**Arguments**

- |                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>object</i>       | an object inheriting from class <i>groupedData</i> .                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>formula</i>      | a formula of the form <i>resp</i> ~ <i>cov</i>   <i>group</i> where <i>resp</i> is the response, <i>cov</i> is the primary covariate, and <i>group</i> is the grouping factor. The expression 1 can be used for the primary covariate when there is no other suitable candidate. Multiple nested grouping factors can be listed separated by the / symbol as in fact1/fact2. In an expression like this the <i>fact2</i> factor is nested within the <i>fact1</i> factor. |
| <i>data</i>         | a data frame in which the expressions in <i>formula</i> can be evaluated. The resulting <i>groupedData</i> object will consist of the same data values in the same order but with additional attributes.                                                                                                                                                                                                                                                                  |
| <i>order.groups</i> | an optional logical value, or list of logical values, indicating if the grouping factors should be converted to ordered factors according to the function <i>FUN</i> applied to the response from each group. If multiple levels of grouping are present, this argument can be either a single logical value (which will be repeated for all grouping levels) or a list of logical values. If no names are assigned to the                                                |

list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). Ordering within a level of grouping is done within the levels of the grouping factors which are outer to it. Changing the grouping factor to an ordered factor does not affect the ordering of the rows in the data frame but it does affect the order of the panels in a trellis display of the data or models fitted to the data. Defaults to TRUE.

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FUN    | an optional summary function that will be applied to the values of the response for each level of the grouping factor, when <code>order.groups = TRUE</code> , to determine the ordering. Defaults to the <code>max</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| outer  | an optional one-sided formula, or list of one-sided formulas, indicating covariates that are outer to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. When plotting a groupedData object, the argument <code>outer = TRUE</code> causes the panels to be determined by the outer formula. The points within the panels are associated by level of the grouping factor. Defaults to NULL, meaning that no outer covariates are present. |
| inner  | an optional one-sided formula, or list of one-sided formulas, indicating covariates that are inner to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An inner covariate can change within the sets of rows defined by the grouping factor. An inner formula can be used to associate points in a plot of a groupedData object. Defaults to NULL, meaning that no inner covariates are present.                                                                                                                                                                                                                                                            |
| labels | an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either label can be omitted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| units  | an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either units string can be omitted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### Value

an object of one of the classes `nfnGroupedData`, `nffGroupedData`, or `nmGroupedData`, and also inheriting from classes `groupedData` and `data.frame`.

### Examples

```
Orth.new <- # create a new copy of the groupedData object
groupedData(distance ~ age | Subject,
 data = as.data.frame(Orthodont),
 FUN = mean,
 outer = ~ Sex,
 labels = list(x = "Age",
 y = "Distance from pituitary to pterygomaxillary fissure"),
 units = list(x = "(yr)", y = "(mm)"))

Not run:
plot(Orth.new) # trellis plot by Subject

End(Not run)
formula(Orth.new) # extractor for the formula
gsummary(Orth.new) # apply summary by Subject
fm1 <- lme(Orth.new) # fixed and groups formulae extracted from object
Orthodont2 <- update(Orthodont, FUN = mean)
```

**gsummary**

*Summarize by Groups*

### Description

Provide a summary of the variables in a data frame by groups of rows. This is most useful with a `groupedData` object to examine the variables by group.

### Usage

```
gsummary(object, FUN, omitGroupingFactor, form, level,
 groups, invariantsOnly, ...)
```

### Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object to be summarized - usually a <code>groupedData</code> object or a <code>data.frame</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>FUN</code>    | an optional summary function or a list of summary functions to be applied to each variable in the frame. The function or functions are applied only to variables in <code>object</code> that vary within the groups defined by <code>groups</code> . Invariant variables are always summarized by group using the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will |

be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

#### omitGroupingFactor

an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary but the levels of the grouping factor will continue to be used as the row names for the data frame that is produced by the summary. Defaults to FALSE.

#### form

an optional one-sided formula that defines the groups. When this formula is given, the right-hand side is evaluated in object, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to formula(object).

#### level

an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.

#### groups

an optional factor that will be used to split the rows into groups. Defaults to getGroups(object, form, level).

#### invariantsOnly

an optional logical value. When TRUE only those covariates that are invariant within each group will be summarized. The summary value for the group is always the unique value taken on by that covariate within the group. The columns in the summary are of the same class as the corresponding columns in object. By definition, the grouping factor itself must be an invariant. When combined with omitGroupingFactor = TRUE, this option can be used to discover if there are invariant covariates in the data frame. Defaults to FALSE.

#### ...

optional additional arguments to the summary functions that are invoked on the variables by group. Often it is helpful to specify na.rm = TRUE.

### Value

A data.frame with one row for each level of the grouping factor. The number of columns is at most the number of columns in object.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### Examples

```
gsummary(Orthodont) # default summary by Subject
gsummary with invariantsOnly = TRUE and omitGroupingFactor = TRUE
determines whether there are covariates like Sex that are invariant
within the repeated observations on the same Subject.
gsummary(Orthodont, inv = TRUE, omit = TRUE)
```

|-----|--------------------------------------|
| Gun | <i>Methods for firing naval guns</i> |
|-----|--------------------------------------|

---

### Description

The Gun data frame has 36 rows and 4 columns.

### Format

This data frame contains the following columns:

**rounds** a numeric vector

**Method** a factor with levels M1 M2

**Team** an ordered factor with levels T1S < T3S < T2S < T1A < T2A < T3A < T1H < T3H < T2H

**Physique** an ordered factor with levels Slight < Average < Heavy

### Details

Hicks (p.180, 1993) reports data from an experiment on methods for firing naval guns. Gunners of three different physiques (slight, average, and heavy) tested two firing methods. Both methods were tested twice by each of nine teams of three gunners with identical physique. The response was the number of rounds fired per minute.

|-----|------------------------------------------|
| IGF | <i>Radioimmunoassay of IGF-I Protein</i> |
|-----|------------------------------------------|

---

### Description

The IGF data frame has 237 rows and 3 columns.

### Format

This data frame contains the following columns:

**Lot** an ordered factor giving the radioactive tracer lot.

**age** a numeric vector giving the age (in days) of the radioactive tracer.

**conc** a numeric vector giving the estimated concentration of IGF-I protein (ng/ml)

### Details

Davidian and Giltinan (1995) describe data obtained during quality control radioimmunoassays for ten different lots of radioactive tracer used to calibrate the Insulin-like Growth Factor (IGF-I) protein concentration measurements.

**Initialize****Initialize Object**

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, `lmeStruct`, `reStruct`, and `varFunc`.

**Usage**

```
Initialize(object, data, ...)
```

**Arguments**

|                     |                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | any object requiring initialization, e.g. "plug-in" structures such as <code>corStruct</code> and <code>varFunc</code> objects. |
| <code>data</code>   | a data frame to be used in the initialization procedure.                                                                        |
| ...                 | some methods for this generic function require additional arguments.                                                            |

**Value**

an initialized object with the same class as `object`. Changes introduced by the initialization procedure will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

`Initialize.varFunc`, `isInitialized`

**Examples**

```
see the method function documentation
```

---

**Initialize.corStruct** *Initialize corStruct Object*

---

**Description**

This method initializes object by evaluating its associated covariate(s) and grouping factor, if any is present, in data, calculating various dimensions and constants used by optimization algorithms involving corStruct objects (see the appropriate Dim method documentation), and assigning initial values for the coefficients in object, if none were present.

**Usage**

```
S3 method for class 'corStruct'
Initialize(object, data, ...)
```

**Arguments**

- |        |                                                                                              |
|--------|----------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>corStruct</code> representing a correlation structure. |
| data   | a data frame in which to evaluate the variables defined in <code>formula(object)</code> .    |
| ...    | this argument is included to make this method compatible with the generic.                   |

**Value**

an initialized object with the same class as object representing a correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

cs1 <- corAR1(form = ~ 1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
```

---

**Initialize.glsStruct** *Initialize a glsStruct Object*

---

**Description**

The individual linear model components of the `glsStruct` list are initialized.

**Usage**

```
S3 method for class 'glsStruct'
Initialize(object, data, control, ...)
```

**Arguments**

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.                                                                                                                                                                                                                                           |
| <code>data</code>    | a data frame in which to evaluate the variables defined in <code>formula(object)</code> .                                                                                                                                                                                                                                                                                                                           |
| <code>control</code> | an optional list with control parameters for the initialization and optimization algorithms used in <code>gls</code> . Defaults to <code>list(singular.ok = FALSE, qrTol = .Machine\$single.eps)</code> , implying that linear dependencies are not allowed in the model and that the tolerance for detecting linear dependencies among the columns of the regression matrix is <code>.Machine\$single.eps</code> . |
| <code>...</code>     | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                           |

**Value**

a `glsStruct` object similar to `object`, but with initialized model components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

**Initialize.lmeStruct** *Initialize an lmeStruct Object*

---

**Description**

The individual linear mixed-effects model components of the `lmeStruct` list are initialized.

**Usage**

```
S3 method for class 'lmeStruct'
Initialize(object, data, groups, conLin, control, ...)
```

**Arguments**

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | an object inheriting from class <code>lmeStruct</code> , representing a list of linear mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.                                                                                                                                                                                                                                                                                         |
| <code>data</code>    | a data frame in which to evaluate the variables defined in <code>formula(object)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>groups</code>  | a data frame with the grouping factors corresponding to the <code>lme</code> model associated with <code>object</code> as columns, sorted from innermost to outermost grouping level.                                                                                                                                                                                                                                                                                                                     |
| <code>conLin</code>  | an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying <code>lme</code> model. Defaults to <code>attr(object, "conLin")</code> .                                                                                                                             |
| <code>control</code> | an optional list with control parameters for the initialization and optimization algorithms used in <code>lme</code> . Defaults to <code>list(niterEM=20, gradHess=TRUE)</code> , implying that 20 EM iterations are to be used in the derivation of initial estimates for the coefficients of the <code>reStruct</code> component of <code>object</code> and, if possible, numerical gradient vectors and Hessian matrices for the log-likelihood function are to be used in the optimization algorithm. |
| <code>...</code>     | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Value**

an `lmeStruct` object similar to `object`, but with initialized model components.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**See Also**

[lme](#), [Initialize.reStruct](#), [Initialize.corStruct](#), [Initialize.varFunc](#), [Initialize](#)

[Initialize.reStruct](#)    *Initialize reStruct Object*

**Description**

Initial estimates for the parameters in the `pdMat` objects forming `object`, which have not yet been initialized, are obtained using the methodology described in Bates and Pinheiro (1998). These estimates may be refined using a series of EM iterations, as described in Bates and Pinheiro (1998). The number of EM iterations to be used is defined in `control`.

**Usage**

```
S3 method for class 'reStruct'
Initialize(object, data, conLin, control, ...)
```

**Arguments**

|         |                                                                                                                                                                                                                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.                                                                                                                                               |
| data    | a data frame in which to evaluate the variables defined in <code>formula(object)</code> .                                                                                                                                                                                                             |
| conLin  | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.                                                                  |
| control | an optional list with a single component <code>niterEM</code> controlling the number of iterations for the EM algorithm used to refine initial parameter estimates. It is given as a list for compatibility with other <code>Initialize</code> methods. Defaults to <code>list(niterEM = 20)</code> . |
| ...     | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                             |

**Value**

an `reStruct` object similar to `object`, but with all `pdMat` components initialized.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[reStruct](#), [pdMat](#), [Initialize](#)

`Initialize.varFunc`      *Initialize varFunc Object*

**Description**

This method initializes `object` by evaluating its associated covariate(s) and grouping factor, if any is present, in `data`; determining if the covariate(s) need to be updated when the values of the coefficients associated with `object` change; initializing the log-likelihood and the weights associated with `object`; and assigning initial values for the coefficients in `object`, if none were present. The covariate(s) will only be initialized if no update is needed when `coef(object)` changes.

**Usage**

```
S3 method for class 'varFunc'
Initialize(object, data, ...)
```

**Arguments**

|        |                                                                                                    |
|--------|----------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>varFunc</code> , representing a variance function structure. |
| data   | a data frame in which to evaluate the variables named in <code>formula(object)</code> .            |
| ...    | this argument is included to make this method compatible with the generic.                         |

**Value**

an initialized object with the same class as `object` representing a variance function structure.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

vf1 <- varPower(form = ~ age | Sex)
vf1 <- Initialize(vf1, Orthodont)
```

**intervals**

*Confidence Intervals on Coefficients*

**Description**

Confidence intervals on the parameters associated with the model represented by `object` are obtained. This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

**Usage**

```
intervals(object, level, ...)
```

**Arguments**

|        |                                                                                |
|--------|--------------------------------------------------------------------------------|
| object | a fitted model object from which parameter estimates can be extracted.         |
| level  | an optional numeric value for the interval confidence level. Defaults to 0.95. |
| ...    | some methods for the generic may require additional arguments.                 |

**Value**

will depend on the method function used; see the appropriate documentation.

---

intervals.gls*Confidence Intervals on gls Parameters*

---

**Description**

Approximate confidence intervals for the parameters in the linear model represented by object are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale.

**Usage**

```
S3 method for class 'gls'
intervals(object, level, which, ...)
```

**Arguments**

- |        |                                                                                                                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model.                                                                                                                                                                             |
| level  | an optional numeric value for the interval confidence level. Defaults to 0.95.                                                                                                                                                                                                               |
| which  | an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "coef" for the linear model coefficients only. Defaults to "all". |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                    |

**Value**

a list with components given by data frames with rows corresponding to parameters and columns lower, est., and upper representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

- |           |                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------|
| coef      | linear model coefficients, only present when which is not equal to "var-cov".                                                     |
| corStruct | correlation parameters, only present when which is not equal to "coef" and a correlation structure is used in object.             |
| varFunc   | variance function parameters, only present when which is not equal to "coef" and a variance function structure is used in object. |
| sigma     | residual standard error.                                                                                                          |

*Confidence Intervals on lme Parameters*

**Description**

Approximate confidence intervals for the parameters in the linear mixed-effects model represented by object are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale. The pdNatural parametrization is used for general positive-definite matrices.

**Usage**

```
S3 method for class 'lme'
intervals(object, level, which, ...)
```

**Arguments**

- |        |                                                                                                                                                                                                                                                                                   |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                              |
| level  | an optional numeric value with the confidence level for the intervals. Defaults to 0.95.                                                                                                                                                                                          |
| which  | an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are "all" for all parameters, "var-cov" for the variance-covariance parameters only, and "fixed" for the fixed effects only. Defaults to "all". |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                         |

**Value**

a list with components given by data frames with rows corresponding to parameters and columns `lower`, `est.`, and `upper` representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

- |          |                                                                                                 |
|----------|-------------------------------------------------------------------------------------------------|
| fixed    | fixed effects, only present when which is not equal to "var-cov".                               |
| reStruct | random effects variance-covariance parameters, only present when which is not equal to "fixed". |

|           |                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| corStruct | within-group correlation parameters, only present when which is not equal to "fixed" and a correlation structure is used in object.             |
| varFunc   | within-group variance function parameters, only present when which is not equal to "fixed" and a variance function structure is used in object. |
| sigma     | within-group standard deviation.                                                                                                                |

**intervals.lmList**

*Confidence Intervals on lmList Coefficients*

**Description**

Confidence intervals on the linear model coefficients are obtained for each `lm` component of `object` and organized into a three dimensional array. The first dimension corresponding to the names of the `object` components. The second dimension is given by `lower`, `est.`, and `upper` corresponding, respectively, to the lower confidence limit, estimated coefficient, and upper confidence limit. The third dimension is given by the coefficients names.

**Usage**

```
S3 method for class 'lmList'
intervals(object, level, pool, ...)
```

**Arguments**

|        |                                                                                                                                                              |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.                                    |
| level  | an optional numeric value with the confidence level for the intervals. Defaults to 0.95.                                                                     |
| pool   | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> . |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                    |

**Value**

a three dimensional array with the confidence intervals and estimates for the coefficients of each lm component of object.

fm1 <- lmList(distance ~ age | Subject, Orthodont)
intervals(fm1)
```

**isBalanced**

*Check a Design for Balance*

**Description**

Check the design of the experiment or study for balance.

**Usage**

```
isBalanced(object, countOnly, level)
```

**Arguments**

|                  |                                                                                                                                                                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b>    | A groupedData object containing a data frame and a formula that describes the roles of variables in the data frame. The object will have one or more nested grouping factors and a primary covariate.                             |
| <b>countOnly</b> | A logical value indicating if the check for balance should only consider the number of observations at each level of the grouping factor(s). Defaults to FALSE.                                                                   |
| <b>level</b>     | an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level. |

**Details**

A design is balanced with respect to the grouping factor(s) if there are the same number of observations at each distinct value of the grouping factor or each combination of distinct levels of the nested grouping factors. If countOnly is FALSE the design is also checked for balance with respect to the primary covariate, which is often the time of the observation. A design is balanced with respect to the grouping factor and the covariate if the number of observations at each distinct level (or combination of levels for nested factors) is constant and the times at which the observations are taken (in general, the values of the primary covariates) also are constant.

**Value**

TRUE or FALSE according to whether the data are balanced or not

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[table](#), [groupedData](#)

**Examples**

```
isBalanced(Orthodont) # should return TRUE
isBalanced(Orthodont, countOnly = TRUE) # should return TRUE
isBalanced(Pixel) # should return FALSE
isBalanced(Pixel, level = 1) # should return FALSE
```

---

isInitialized

*Check if Object is Initialized*

---

**Description**

Checks if object has been initialized (generally through a call to [Initialize](#)), by searching for components and attributes which are modified during initialization.

**Usage**

`isInitialized(object)`

**Arguments**

object            any object requiring initialization.

**Value**

a logical value indicating whether object has been initialized.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

[Initialize](#)

**Examples**

```
pd1 <- pdDiag(~age)
isInitialized(pd1)
```

**LDEsysMat***Generate system matrix for LDEs***Description**

Generate the system matrix for the linear differential equations determined by a compartment model.

**Usage**

```
LDEsysMat(pars, incidence)
```

**Arguments**

- |                        |                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pars</code>      | a numeric vector of parameter values.                                                                                                                                                                                                                                                                                                                                         |
| <code>incidence</code> | an integer matrix with columns named <code>From</code> , <code>To</code> , and <code>Par</code> . Values in the <code>Par</code> column must be in the range 1 to <code>length(pars)</code> . Values in the <code>From</code> column must be between 1 and the number of compartments. Values in the <code>To</code> column must be between 0 and the number of compartments. |

**Details**

A compartment model describes material transfer between  $k$  in a system of  $k$  compartments to a linear system of differential equations. Given a description of the system and a vector of parameter values this function returns the system matrix.

This function is intended for use in a general system for solving compartment models, as described in Bates and Watts (1988).

**Value**

A  $k$  by  $k$  numeric matrix.

**Author(s)**

Douglas Bates <bates@stat.wisc.edu>

**References**

Bates, D. M. and Watts, D. G. (1988), *Nonlinear Regression Analysis and Its Applications*, Wiley, New York.

**Examples**

```
incidence matrix for a two compartment open system
incidence <-
 matrix(c(1,1,2,2,2,1,3,2,0), ncol = 3, byrow = TRUE,
 dimnames = list(NULL, c("Par", "From", "To")))
incidence
LDEsysMat(c(1.2, 0.3, 0.4), incidence)
```

lme

*Linear Mixed-Effects Models*

## Description

This generic function fits a linear mixed-effects model in the formulation described in Laird and Ware (1982) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

## Usage

```
lme(fixed, data, random, correlation, weights, subset, method,
 na.action, control, contrasts = NULL, keep.data = TRUE)
S3 method for class 'lme'
update(object, fixed., ..., evaluate = TRUE)
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>object</b>      | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>fixed</b>       | a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a <code>~</code> operator and the terms, separated by <code>+</code> operators, on the right, an <code>lmList</code> object, or a <code>groupedData</code> object. The method functions <code>lme.lmList</code> and <code>lme.groupedData</code> are documented separately.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>fixed.</b>      | Changes to the fixed-effects formula – see <code>update.formula</code> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>data</b>        | an optional data frame containing the variables named in <code>fixed</code> , <code>random</code> , <code>correlation</code> , <code>weights</code> , and <code>subset</code> . By default the variables are taken from the environment from which <code>lme</code> is called.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>random</b>      | optionally, any of the following: (i) a one-sided formula of the form <code>~ x1 + ... + xn   g1/.../gm</code> , with <code>x1 + ... + xn</code> specifying the model for the random effects and <code>g1/.../gm</code> the grouping structure ( <code>m</code> may be equal to 1, in which case no <code>/</code> is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form <code>~ x1 + ... + xn   g</code> , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form <code>~ x1 + ... + xn</code> , or a <code>pdMat</code> object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or <code>pdMat</code> objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class <code>groupedData</code> ; (iv) a named list of formulas or <code>pdMat</code> objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an <code>reStruct</code> object. See the documentation on <code>pdClasses</code> for a description of the available <code>pdMat</code> classes. Defaults to a formula consisting of the right hand side of <code>fixed</code> . |
| <b>correlation</b> | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|           |                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| weights   | an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors. |
| subset    | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                    |
| method    | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".                                                                                                                                                                                                                        |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes lme to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                               |
| control   | a list of control values for the estimation algorithm to replace the default values returned by the function lmeControl. Defaults to an empty list.                                                                                                                                                                                                                             |
| contrasts | an optional list. See the contrasts.arg of model.matrix.default.                                                                                                                                                                                                                                                                                                                |
| keep.data | logical: should the data argument (if supplied and a data frame) be saved as part of the model object?                                                                                                                                                                                                                                                                          |
| ...       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                       |
| evaluate  | If TRUE evaluate the new call else return the call.                                                                                                                                                                                                                                                                                                                             |

### Value

an object of class lme representing the linear mixed-effects model fit. Generic functions such as print, plot and summary have methods to show the results of the fit. See lmeObject for the components of the fit. The functions resid, coef, fitted, fixed.effects, and random.effects can be used to extract some of its components.

### Note

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

The computational methods follow the general framework of Lindstrom and Bates (1988). The model formulation is described in Laird and Ware (1982). The variance-covariance parametrizations are described in Pinheiro and Bates (1996). The different correlation structures available for the correlation argument are described in Box, Jenkins and Reinsel (1994), Littell *et al* (1996), and Venables and Ripley, (2002). The use of variance functions for linear and nonlinear mixed effects models is presented in detail in Davidian and Giltinan (1995).

## Examples

```
fm1 <- lme(distance ~ age, data = Orthodont) # random is ~ age
fm2 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
summary(fm1)
summary(fm2)
```

**lme.groupedData**      *LME fit from groupedData Object*

## Description

The response variable and primary covariate in `formula(fixed)` are used to construct the fixed effects model formula. This formula and the `groupedData` object are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.

## Usage

```
S3 method for class 'groupedData'
lme(fixed, data, random, correlation, weights,
 subset, method, na.action, control, contrasts, keep.data = TRUE)
```

## Arguments

|                    |                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <code>fixed</code> | a data frame inheriting from class <code>groupedData</code> .                                               |
| <code>data</code>  | this argument is included for consistency with the generic function. It is ignored in this method function. |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| random      | optionally, any of the following: (i) a one-sided formula of the form $\sim x_1 + \dots + x_n \mid g_1 / \dots / g_m$ , with $x_1 + \dots + x_n$ specifying the model for the random effects and $g_1 / \dots / g_m$ the grouping structure ( $m$ may be equal to 1, in which case no $/$ is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form $\sim x_1 + \dots + x_n \mid g$ , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form $\sim x_1 + \dots + x_n$ , or a pdMat object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or pdMat objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class <code>groupedData</code> ; (iv) a named list of formulas or pdMat objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an <code>reStruct</code> object. See the documentation on <code>pdClasses</code> for a description of the available pdMat classes. Defaults to a formula consisting of the right hand side of <code>fixed</code> . |
| correlation | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| weights     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| subset      | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| method      | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| na.action   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| control     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| contrasts   | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| keep.data   | logical: should the data argument (if supplied and a data frame) be saved as part of the model object?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### Value

an object of class `lme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

The computational methods follow on the general framework of Lindstrom, M.J. and Bates, D.M. (1988). The model formulation is described in Laird, N.M. and Ware, J.H. (1982). The variance-covariance parametrizations are described in Pinheiro, J.C. and Bates., D.M. (1996). The different correlation structures available for the correlation argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littel, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). The use of variance functions for linear and nonlinear mixed effects models is presented in detail in Davidian, M. and Giltinan, D.M. (1995).

## Examples

```
fm1 <- lme(Orthodont)
summary(fm1)
```

**lme.lmList**

*LME fit from lmList Object*

## Description

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain `fixed` are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.

## Usage

```
S3 method for class 'lmList'
lme(fixed, data, random, correlation, weights, subset, method,
 na.action, control, contrasts, keep.data)
```

## Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>fixed</b>       | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> fits with a common model.                                                                                                                                                                                                                                                                                                                             |
| <b>data</b>        | this argument is included for consistency with the generic function. It is ignored in this method function.                                                                                                                                                                                                                                                                                                                                        |
| <b>random</b>      | an optional one-sided linear formula with no conditioning expression, or a <code>pdMat</code> object with a <code>formula</code> attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of <code>formula(fixed)</code> .                                                                                                                                        |
| <b>correlation</b> | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.                                                                                                                                                    |
| <b>weights</b>     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors. |
| <b>subset</b>      | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                                       |
| <b>method</b>      | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".                                                                                                                                                                                                                                                                                           |
| <b>na.action</b>   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                      |
| <b>control</b>     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.                                                                                                                                                                                                                                                                                  |
| <b>contrasts</b>   | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .                                                                                                                                                                                                                                                                                                                                                        |
| <b>keep.data</b>   | logical: should the <code>data</code> argument (if supplied and a data frame) be saved as part of the model object?                                                                                                                                                                                                                                                                                                                                |

## Value

an object of class `lme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

- The computational methods follow the general framework of Lindstrom and Bates (1988). The model formulation is described in Laird and Ware (1982). The variance-covariance parametrizations are described in Pinheiro and Bates (1996). The different correlation structures available for the correlation argument are described in Box, Jenkins and Reinsel (1994), Littel *et al* (1996), and Venables and Ripley, (2002). The use of variance functions for linear and nonlinear mixed effects models is presented in detail in Davidian and Giltinan (1995).

## Examples

```
fm1 <- lmlist(Orthodont)
fm2 <- lme(fm1)
summary(fm1)
summary(fm2)
```

**lmeControl**

*Control Values for lme Fit*

## Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the control argument to the `lme` function.

## Usage

```
lmeControl(maxIter, msMaxIter, tolerance, niterEM, msMaxEval, msTol,
 msScale, msVerbose, returnObject, gradHess, apVar,
 .relStep, minAbsParApVar, nlmStepMax,
 opt = c("nlminb", "optim"), optimMethod,
 natural, ...)
```

### Arguments

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>maxIter</code>        | maximum number of iterations for the <code>lme</code> optimization algorithm. Default is 50.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>msMaxIter</code>      | maximum number of iterations for the <code>nlm</code> optimization step inside the <code>lme</code> optimization. Default is 50.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>tolerance</code>      | tolerance for the convergence criterion in the <code>lme</code> algorithm. Default is 1e-6.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>niterEM</code>        | number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>msMaxEval</code>      | maximum number of evaluations of the objective function permitted for <code>nlminb</code> . Default is 200.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>msTol</code>          | tolerance for the convergence criterion the first iteration. Default is 1e-7.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>msScale</code>        | scale function passed as the <code>scale</code> argument to the <code>nlm</code> function (see documentation on that function). Default is <code>lmeScale</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>msVerbose</code>      | a logical value passed as the <code>trace</code> argument to <code>nlm</code> (see documentation on that function). Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>returnObject</code>   | a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>gradHess</code>       | a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the <code>nlm</code> optimization. This option is only available when the correlation structure ( <code>corStruct</code> ) and the variance function structure ( <code>varFunc</code> ) have no "varying" parameters and the <code>pdMat</code> classes used in the random effects structure are <code>pdSymm</code> (general positive-definite), <code>pdDiag</code> (diagonal), <code>pdIdent</code> (multiple of the identity), or <code>pdCompSymm</code> (compound symmetry). Default is TRUE. |
| <code>apVar</code>          | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>.relStep</code>       | relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>nlmStepMax</code>     | stepmax value to be passed to <code>nlm</code> . See <code>nlm</code> for details. Default is 100.0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>opt</code>            | the optimizer to be used, either " <code>nlminb</code> " (the default) or " <code>optim</code> ".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>optimMethod</code>    | character - the optimization method to be used with the <code>optim</code> optimizer. The default is "BFGS". An alternative is "L-BFGS-B".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>minAbsParApVar</code> | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>natural</code>        | a logical value indicating whether the <code>pdNatural</code> parametrization should be used for general positive-definite matrices ( <code>pdSymm</code> ) in <code>reStruct</code> , when the approximate covariance matrix of the estimators is calculated. Default is TRUE.                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>            | Further named control arguments to be passed to <code>nlminb</code> (those from <code>abs.tol</code> down) or <code>optim</code> (those except <code>trace</code> and <code>maxit</code> ; <code>reltol</code> : is used only from the second iteration).                                                                                                                                                                                                                                                                                                                                                                               |

### Value

a list with components for each of the possible arguments.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lme](#), [nlm](#), [optim](#), [lmeScale](#)

**Examples**

```
decrease the maximum number iterations in the ms call and
request that information on the evolution of the ms iterations be printed
lmeControl(msMaxIter = 20, msVerbose = TRUE)
```

---

lmeObject

*Fitted lme Object*

---

**Description**

An object returned by the `lme` function, inheriting from class `lme` and representing a fitted linear mixed-effects model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `fixed.effects`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `pairs`, `plot`, `predict`, `print`, `random.effects`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate `lme` object.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>apVar</code>        | an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>lme</code> , this component is equal to <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>call</code>         | a list containing an image of the <code>lme</code> call that produced the object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>coefficients</code> | a list with two components, <code>fixed</code> and <code>random</code> , where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the <code>random</code> list, the columns refer to the random effects and the rows to the groups.                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>contrasts</code>    | a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the <code>lme</code> model, this component will be an empty list.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>dims</code>         | a list with basic dimensions used in the <code>lme</code> fit, including the components <code>N</code> - the number of observations in the data, <code>Q</code> - the number of grouping levels, <code>qvec</code> - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), <code>ngrps</code> - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and <code>ncol</code> - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one). |

|             |                                                                                                                                                                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fitted      | a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping. |
| fixDF       | a list with components <i>X</i> and <i>terms</i> specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.                                |
| groups      | a data frame with the grouping factors as columns. The grouping level increases from left to right.                                                                                                                                              |
| logLik      | the (restricted) log-likelihood at convergence.                                                                                                                                                                                                  |
| method      | the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.                                                                                                                                          |
| modelStruct | an object inheriting from class <i>lmeStruct</i> , representing a list of mixed-effects model components, such as <i>reStruct</i> , <i>corStruct</i> , and <i>varFunc</i> objects.                                                               |
| numIter     | the number of iterations used in the iterative algorithm.                                                                                                                                                                                        |
| residuals   | a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.                                                   |
| sigma       | the estimated within-group error standard deviation.                                                                                                                                                                                             |
| varFix      | an approximate covariance matrix of the fixed effects estimates.                                                                                                                                                                                 |

*lmeScale*

*Scale for lme Optimization*

---

### Description

This function calculates the scales to be used for each coefficient estimated through an *nlm* optimization in the *lme* function. If all initial values are zero, the scale is set to one for all coefficients; else, the scale for a coefficient with non-zero initial value is equal to the inverse of its initial value and the scale for the coefficients with initial value equal to zero is set to the median of the non-zero initial value coefficients.

### Usage

```
lmeScale(start)
```

### Arguments

|       |                                                           |
|-------|-----------------------------------------------------------|
| start | the starting values for the coefficients to be estimated. |
|-------|-----------------------------------------------------------|

### Value

a vector with the scales to be used in *nlm* for estimating the coefficients.

lmeStruct

*Linear Mixed-Effects Structure*

---

**Description**

A linear mixed-effects structure is a list of model components representing different sets of parameters in the linear mixed-effects model. An `lmeStruct` list must contain at least a `reStruct` object, but may also contain `corStruct` and `varFunc` objects. `NULL` arguments are not included in the `lmeStruct` list.

**Usage**

```
lmeStruct(reStruct, corStruct, varStruct)
```

**Arguments**

- |                        |                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>reStruct</code>  | a <code>reStruct</code> representing a random effects structure.                                                    |
| <code>corStruct</code> | an optional <code>corStruct</code> object, representing a correlation structure. Default is <code>NULL</code> .     |
| <code>varStruct</code> | an optional <code>varFunc</code> object, representing a variance function structure. Default is <code>NULL</code> . |

**Value**

a list of model components determining the parameters to be estimated for the associated linear mixed-effects model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
lms1 <- lmeStruct(reStruct(~age), corAR1(), varPower())
```

---

**lmList***List of lm Objects with a Common Model*

---

**Description**

Data is partitioned according to the levels of the grouping factor *g* and individual *lm* fits are obtained for each data partition, using the model defined in *object*.

**Usage**

```
lmList(object, data, level, subset, na.action, pool)
S3 method for class 'lmList'
update(object, formula., ..., evaluate = TRUE)
S3 method for class 'lmList'
print(x, pool, ...)
```

**Arguments**

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b>    | For <i>lmList</i> , either a linear formula object of the form $y \sim x_1 + \dots + x_n   g$ or a <i>groupedData</i> object. In the formula object, <i>y</i> represents the response, $x_1, \dots, x_n$ the covariates, and <i>g</i> the grouping factor specifying the partitioning of the data according to which different <i>lm</i> fits should be performed. The grouping factor <i>g</i> may be omitted from the formula, in which case the grouping structure will be obtained from <i>data</i> , which must inherit from class <i>groupedData</i> . The method function <i>lmList.groupedData</i> is documented separately. For the method <i>update.lmList</i> , <i>object</i> is an object inheriting from class <i>lmList</i> . |
| <b>formula</b>   | (used in <i>update.lmList</i> only) a two-sided linear formula with the common model for the individuals <i>lm</i> fits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>formula.</b>  | Changes to the formula – see <i>update.formula</i> for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>data</b>      | a data frame in which to interpret the variables named in <i>object</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>level</b>     | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>subset</b>    | an optional expression indicating which subset of the rows of <i>data</i> should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>na.action</b> | a function that indicates what should happen when the data contain NAs. The default action ( <i>na.fail</i> ) causes <i>lmList</i> to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>pool</b>      | an optional logical value indicating whether a pooled estimate of the residual standard error should be used in calculations of standard deviations or standard errors for summaries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>x</b>         | an object inheriting from class <i>lmList</i> to be printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>...</b>       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>evaluate</b>  | If TRUE evaluate the new call else return the call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Value

a list of lm objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an lmList object.

### References

### See Also

`lm`, `lme.lmList`, `plot.lmList`, `pooledSD`, `predict.lmList`, `residuals.lmList`, `summary.lmList`

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
summary(fm1)
```

---

lmList.groupedData      *lmList Fit from a groupedData Object*

---

### Description

The response variable and primary covariate in `formula(object)` are used to construct the linear model formula. This formula and the groupedData object are passed as the object and data arguments to `lmList.formula`, together with any other additional arguments in the function call. See the documentation on `lmList.formula` for a description of that function.

### Usage

```
S3 method for class 'groupedData'
lmList(object, data, level, subset, na.action, pool)
```

### Arguments

|                        |                                                                                                                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | a data frame inheriting from class <code>groupedData</code> .                                                                                                                                                                                                                                             |
| <code>data</code>      | this argument is included for consistency with the generic function. It is ignored in this method function.                                                                                                                                                                                               |
| <code>level</code>     | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.                                                                                                                                                                                      |
| <code>subset</code>    | an optional expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |
| <code>na.action</code> | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lmList</code> to print an error message and terminate if there are any incomplete observations.                                                                          |
| <code>pool</code>      | an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for <code>pool</code> in calculations of standard deviations or standard errors for summaries.                                                                                        |

**Value**

a list of `lm` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `lmList` object.

`groupedData`, `lm`, `lme.lmList`, `lmList`, `lmList.formula`

**Examples**

```
fm1 <- lmList(Orthodont)
summary(fm1)
```

`logDet`

*Extract the Logarithm of the Determinant*

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, several `pdMat` classes, and `reStruct`.

**Usage**

```
logDet(object, ...)
```

**Arguments**

|        |                                                                       |
|--------|-----------------------------------------------------------------------|
| object | any object from which a matrix, or list of matrices, can be extracted |
| ...    | some methods for this generic function require additional arguments.  |

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`logLik`, `logDet.corStruct`, `logDet.pdMat`, `logDet.reStruct`

**Examples**

```
see the method function documentation
```

---

**logDet.corStruct**      *Extract corStruct Log-Determinant*

---

**Description**

This method function extracts the logarithm of the determinant of a square-root factor of the correlation matrix associated with object, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with object.

**Usage**

```
S3 method for class 'corStruct'
logDet(object, covariate, ...)
```

**Arguments**

- |           |                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | an object inheriting from class <code>corStruct</code> , representing a correlation structure.                                                                                                                                |
| covariate | an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to <code>getCovariate(object)</code> . |
| ...       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                     |

**Value**

the log-determinant of a square-root factor of the correlation matrix associated with object, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

cs1 <- corAR1(0.3)
logDet(cs1, covariate = 1:4)
```

**logDet.pdMat***Extract Log-Determinant from a pdMat Object***Description**

This method function extracts the logarithm of the determinant of a square-root factor of the positive-definite matrix represented by object.

**Usage**

```
S3 method for class 'pdMat'
logDet(object, ...)
```

**Arguments**

|        |                                                                                               |
|--------|-----------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>pdMat</code> , representing a positive definite matrix. |
| ...    | some methods for this generic require additional arguments. None are used in this method.     |

**Value**

the log-determinant of a square-root factor of the positive-definite matrix represented by object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
pd1 <- pdSymm(diag(1:3))
logDet(pd1)
```

**logDet.reStruct***Extract reStruct Log-Determinants***Description**

Calculates, for each of the `pdMat` components of object, the logarithm of the determinant of a square-root factor.

**Usage**

```
S3 method for class 'reStruct'
logDet(object, ...)
```

**Arguments**

- object            an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of `pdMat` objects.
- ...                some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the log-determinants of square-root factors of the `pdMat` components of `object`.

**Author(s)**

José Pinheiro

**See Also**

**Examples**

```
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
 B = pdDiag(2 * diag(4), form = ~Educ)))
logDet(rs1)
```

`logLik.corStruct`

*Extract corStruct Log-Likelihood*

**Description**

This method function extracts the component of a Gaussian log-likelihood associated with the correlation structure, which is equal to the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the matrix (or matrices) represented by `object`.

**Usage**

```
S3 method for class 'corStruct'
logLik(object, data, ...)
```

**Arguments**

- object            an object inheriting from class `corStruct`, representing a correlation structure.
- data              this argument is included to make this method function compatible with other `logLik` methods and will be ignored.
- ...                some methods for this generic require additional arguments. None are used in this method.

**Value**

the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the correlation matrix (or matrices) represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[logDet.corStruct](#), [logLik.lme](#),

**Examples**

```
cs1 <- corAR1(0.2)
cs1 <- Initialize(cs1, data = Orthodont)
logLik(cs1)
```

**logLik.glsStruct**      *Log-Likelihood of a glsStruct Object*

**Description**

`Pars` is used to update the coefficients of the model components of `object` and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the `settings` attribute of `object`.

**Usage**

```
S3 method for class 'glsStruct'
logLik(object, Pars, conLin, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.                                                                                                                                                                                           |
| <code>Pars</code>   | the parameter values at which the (restricted) log-likelihood is to be evaluated.                                                                                                                                                                                                                                                                                   |
| <code>conLin</code> | an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying linear model. Defaults to <code>attr(object, "conLin")</code> . |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                           |

**Value**

the (restricted) log-likelihood for the linear model described by `object`, evaluated at `Pars`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

**logLik.gnls***Log-Likelihood of a gnls Object*

---

**Description**

Returns the log-likelihood value of the nonlinear model represented by `object` evaluated at the estimated coefficients.

**Usage**

```
S3 method for class 'gnls'
logLik(object, REML, ...)
```

**Arguments**

|                     |                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>gnls</code> , representing a generalized nonlinear least squares fitted model. |
| <code>REML</code>   | an logical value for consistency with <code>logLik.gls</code> , but only <code>FALSE</code> is accepted..            |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                            |

**Value**

the log-likelihood of the linear model represented by `object` evaluated at the estimated coefficients.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

`logLik.lme`

*Log-Likelihood of an lme Object*

**Description**

If `REML=FALSE`, returns the log-likelihood value of the linear mixed-effects model represented by `object` evaluated at the estimated coefficients; else, the restricted log-likelihood evaluated at the estimated coefficients is returned.

**Usage**

```
S3 method for class 'lme'
logLik(object, REML, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                  |
| <code>REML</code>   | an optional logical value. If <code>TRUE</code> the restricted log-likelihood is returned, else, if <code>FALSE</code> , the log-likelihood is returned. Defaults to the method of estimation used, that is <code>TRUE</code> if and only <code>object</code> was fitted with <code>method = "REML"</code> (the default for these fitting functions). |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                             |

**Value**

the (restricted) log-likelihood of the model represented by object evaluated at the estimated coefficients.

S3 method for class 'lmeStruct'
logLik(object, Pars, conLin, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>lmeStruct</code> , representing a list of linear mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.                                                                                                                                                             |
| <code>Pars</code>   | the parameter values at which the (restricted) log-likelihood is to be evaluated.                                                                                                                                                                                                                                                                                             |
| <code>conLin</code> | an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying <code>lme</code> model. Defaults to <code>attr(object, "conLin")</code> . |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                     |

**Value**

the (restricted) log-likelihood for the linear mixed-effects model described by `object`, evaluated at `Pars`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lme](#), [lmeStruct](#), [logLik.lme](#)

[logLik.lmList](#)

*Log-Likelihood of an lmList Object*

**Description**

If `pool=FALSE`, the (restricted) log-likelihoods of the `lm` components of `object` are summed together. Else, the (restricted) log-likelihood of the `lm` fit with different coefficients for each level of the grouping factor associated with the partitioning of the `object` components is obtained.

**Usage**

```
S3 method for class 'lmList'
logLik(object, REML, pool, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.                                                                         |
| <code>REML</code>   | an optional logical value. If <code>TRUE</code> the restricted log-likelihood is returned, else, if <code>FALSE</code> , the log-likelihood is returned. Defaults to <code>FALSE</code> .         |
| <code>pool</code>   | an optional logical value indicating whether all <code>lm</code> components of <code>object</code> may be assumed to have the same error variance. Default is <code>attr(object, "pool")</code> . |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                         |

**Value**

either the sum of the (restricted) log-likelihoods of each `lm` component in `object`, or the (restricted) log-likelihood for the `lm` fit with separate coefficients for each component of `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

|                 |                                          |
|-----------------|------------------------------------------|
| logLik.reStruct | <i>Calculate reStruct Log-Likelihood</i> |
|-----------------|------------------------------------------|

---

## Description

Calculates the log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)`. The `settings` attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods are described in Bates and Pinheiro (1998).

## Usage

```
S3 method for class 'reStruct'
logLik(object, conLin, ...)
```

## Arguments

- |                     |                                                                                                                                                                                                                                                                    |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.                                                                                                            |
| <code>conLin</code> | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and "logLik", corresponding to the log-likelihood of the underlying model. |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                          |

## Value

the log-likelihood, or restricted log-likelihood, of linear mixed-effects model represented by `object` and `conLin`, evaluated at `coef{object}`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

**logLik.varFunc**      *Extract varFunc logLik*

---

## Description

This method function extracts the component of a Gaussian log-likelihood associated with the variance function structure represented by `object`, which is equal to the sum of the logarithms of the corresponding weights.

## Usage

```
S3 method for class 'varFunc'
logLik(object, data, ...)
```

## Arguments

- `object`      an object inheriting from class `varFunc`, representing a variance function structure.
- `data`      this argument is included to make this method function compatible with other `logLik` methods and will be ignored.
- `...`      some methods for this generic require additional arguments. None are used in this method.

## Value

the sum of the logarithms of the weights corresponding to the variance function structure represented by `object`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Machines***Productivity Scores for Machines and Workers*

---

**Description**

The Machines data frame has 54 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Worker** an ordered factor giving the unique identifier for the worker.

**Machine** a factor with levels A, B, and C identifying the machine brand.

**score** a productivity score.

**Details**

Data on an experiment to compare three brands of machines used in an industrial process are presented in Milliken and Johnson (p. 285, 1992). Six workers were chosen randomly among the employees of a factory to operate each machine three times. The response is an overall productivity score taking into account the number and quality of components produced.

**MathAchieve***Mathematics achievement scores*

---

**Description**

The MathAchieve data frame has 7185 rows and 6 columns.

**Format**

This data frame contains the following columns:

**School** an ordered factor identifying the school that the student attends

**Minority** a factor with levels No Yes indicating if the student is a member of a minority racial group.

**Sex** a factor with levels Male Female

**SES** a numeric vector of socio-economic status.

**MathAch** a numeric vector of mathematics achievement scores.

**MEANSES** a numeric vector of the mean SES for the school.

## Details

Each row in this data frame contains the data for one student.

## Examples

```
summary(MathAchieve)
```

**MathAchSchool**

*School demographic data for MathAchieve*

## Description

The MathAchSchool data frame has 160 rows and 7 columns.

## Format

This data frame contains the following columns:

- School** a factor giving the school on which the measurement is made.
- Size** a numeric vector giving the number of students in the school
- Sector** a factor with levels Public Catholic
- PRACAD** a numeric vector giving the percentage of students on the academic track
- DISCLIM** a numeric vector measuring the discrimination climate
- HIMINTY** a factor with levels 0 1
- MEANSES** a numeric vector giving the mean SES score.

## Details

These variables give the school-level demographic data to accompany the MathAchieve data.

**Matrix**

*Assign Matrix Values*

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `pdMat`, `pdBlocked`, and `reStruct`.

## Usage

```
matrix(object) <- value
```

## Arguments

- |               |                                                                                                                                                                                  |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b> | any object to which <code>as.matrix</code> can be applied.                                                                                                                       |
| <b>value</b>  | a matrix, or list of matrices, with the same dimensions as <code>as.matrix(object)</code> with the new values to be assigned to the matrix associated with <code>object</code> . |

**Value**

will depend on the method function; see the appropriate documentation.

Matrix.pdMat

*Assign Matrix to a pdMat Object*

---

**Description**

The positive-definite matrix represented by `object` is replaced by `value`. If the original matrix had row and/or column names, the corresponding names for `value` can either be `NULL`, or a permutation of the original names.

**Usage**

```
S3 replacement method for class 'pdMat'
matrix(object) <- value
```

**Arguments**

|        |                                                                                                                                                                                    |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>pdMat</code> , representing a positive definite matrix.                                                                                      |
| value  | a matrix with the new values to be assigned to the positive-definite matrix represented by <code>object</code> . Must have the same dimensions as <code>as.matrix(object)</code> . |

**Value**

a `pdMat` object similar to `object`, but with its coefficients modified to produce the matrix in `value`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[pdMat](#), ["matrix<-"](#)

**Examples**

```
pd1 <- pdSymm(diag(3))
matrix(pd1) <- diag(1:3)
pd1
```

---

|                              |                                 |
|------------------------------|---------------------------------|
| <code>Matrix.reStruct</code> | <i>Assign reStruct Matrices</i> |
|------------------------------|---------------------------------|

---

## Description

The individual matrices in `value` are assigned to each `pdMat` component of `object`, in the order they are listed. The new matrices must have the same dimensions as the matrices they are meant to replace.

## Usage

```
S3 replacement method for class 'reStruct'
matrix(object) <- value
```

## Arguments

- |                     |                                                                                                                                                              |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.      |
| <code>value</code>  | a matrix, or list of matrices, with the new values to be assigned to the matrices associated with the <code>pdMat</code> components of <code>object</code> . |

## Value

A `reStruct` object similar to `object`, but with the coefficients of the individual `pdMat` components modified to produce the matrices listed in `value`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[reStruct](#), [pdMat](#), ["matrix<-"](#)

## Examples

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
matrix(rs1) <- list(diag(2), 3)
```

---

|                   |                           |
|-------------------|---------------------------|
| <code>Meat</code> | <i>Tenderness of meat</i> |
|-------------------|---------------------------|

---

## Description

The `Meat` data frame has 30 rows and 4 columns.

## Format

This data frame contains the following columns:

**Storage** an ordered factor specifying the storage treatment - 1 (0 days), 2 (1 day), 3 (2 days), 4 (4 days), 5 (9 days), and 6 (18 days)

**score** a numeric vector giving the tenderness score of beef roast.

**Block** an ordered factor identifying the muscle from which the roast was extracted with levels II < V < I < III < IV

**Pair** an ordered factor giving the unique identifier for each pair of beef roasts with levels II-1 < ... < IV-1

## Details

Cochran and Cox (section 11.51, 1957) describe data from an experiment conducted at Iowa State College (Paul, 1943) to compare the effects of length of cold storage on the tenderness of beef roasts. Six storage periods ranging from 0 to 18 days were used. Thirty roasts were scored by four judges on a scale from 0 to 10, with the score increasing with tenderness. The response was the sum of all four scores. Left and right roasts from the same animal were grouped into pairs, which were further grouped into five blocks, according to the muscle from which they were extracted. Different storage periods were applied to each roast within a pair according to a balanced incomplete block design.

Milk

*Protein content of cows' milk*

## Description

The Milk data frame has 1337 rows and 4 columns.

## Format

This data frame contains the following columns:

**protein** a numeric vector giving the protein content of the milk.

**Time** a numeric vector giving the time since calving (weeks).

**Cow** an ordered factor giving a unique identifier for each cow.

**Diet** a factor with levels barley, barley+lupins, and lupins identifying the diet for each cow.

## Details

Diggle, Liang, and Zeger (1994) describe data on the protein content of cows' milk in the weeks following calving. The cattle are grouped according to whether they are fed a diet with barley alone, with barley and lupins, or with lupins alone.

## Source

Diggle, Peter J., Liang, Kung-Yee and Zeger, Scott L. (1994), *Analysis of longitudinal data*, Oxford University Press, Oxford.

---

**model.matrix.reStruct** *reStruct Model Matrix*

---

## Description

The model matrices for each element of `formula(object)`, calculated using `data`, are bound together column-wise. When multiple grouping levels are present (i.e. when `length(object) > 1`), the individual model matrices are combined from innermost (at the leftmost position) to outermost (at the rightmost position).

## Usage

```
S3 method for class 'reStruct'
model.matrix(object, data, contrast, ...)
```

## Arguments

- |          |                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object   | an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.                                                                                                                                                                                                                                                                      |
| data     | a data frame in which to evaluate the variables defined in <code>formula(object)</code> .                                                                                                                                                                                                                                                                                                                                    |
| contrast | an optional named list specifying the contrasts to be used for representing the factor variables in <code>data</code> . The components names should match the names of the variables in <code>data</code> for which the contrasts are to be specified. The components of this list will be used as the <code>contrasts</code> attribute of the corresponding factor. If missing, the default contrast specification is used. |
| ...      | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                    |

## Value

a matrix obtained by binding together, column-wise, the model matrices for each element of `formula(object)`.

|        |                                             |
|--------|---------------------------------------------|
| Muscle | <i>Contraction of heart muscle sections</i> |
|--------|---------------------------------------------|

---

**Description**

The Muscle data frame has 60 rows and 3 columns.

**Format**

This data frame contains the following columns:

- Strip** an ordered factor indicating the strip of muscle being measured.
- conc** a numeric vector giving the concentration of CaCl<sub>2</sub>
- length** a numeric vector giving the shortening of the heart muscle strip.

**Details**

Baumann and Waldvogel (1963) describe data on the shortening of heart muscle strips dipped in a CaCl<sub>2</sub> solution. The muscle strips are taken from the left auricle of a rat's heart.

**Source**

Baumann, F. and Waldvogel, F. (1963), La restitution pastsystolique de la contraction de l'oreillette gauche du rat. Effets de divers ions et de l'acetylcholine, *Helvetica Physiologica Acta*, **21**.

|       |                                        |
|-------|----------------------------------------|
| Names | <i>Names Associated with an Object</i> |
|-------|----------------------------------------|

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `formula`, `modelStruct`, `pdBlocked`, `pdMat`, and `reStruct`.

**Usage**

```
Names(object, ...)
Names(object, ...) <- value
```

**Arguments**

- |                     |                                                                      |
|---------------------|----------------------------------------------------------------------|
| <code>object</code> | any object for which names can be extracted and/or assigned.         |
| <code>...</code>    | some methods for this generic function require additional arguments. |
| <code>value</code>  | names to be assigned to <code>object</code> .                        |

**Value**

will depend on the method function used; see the appropriate documentation.

## SIDE EFFECTS

On the left side of an assignment, sets the names associated with object to value, which must have an appropriate length.

## Note

If names were generic, there would be no need for this generic function.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
see the method function documentation
```

**Names.formula**

*Extract Names from a formula*

## Description

This method function returns the names of the terms corresponding to the right hand side of object (treated as a linear formula), obtained as the column names of the corresponding `model.matrix`.

## Usage

```
S3 method for class 'formula'
Names(object, data, exclude, ...)
```

## Arguments

|                      |                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | an object inheriting from class <code>formula</code> .                                                                                                                                      |
| <code>data</code>    | an optional data frame containing the variables specified in <code>object</code> . By default the variables are taken from the environment from which <code>Names.formula</code> is called. |
| <code>exclude</code> | an optional character vector with names to be excluded from the returned value. Default is <code>c("pi", ".")</code> .                                                                      |
| <code>...</code>     | some methods for this generic require additional arguments. None are used in this method.                                                                                                   |

## Value

a character vector with the column names of the `model.matrix` corresponding to the right hand side of `object` which are not listed in `excluded`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

Names.pdBlocked

*Names of a pdBlocked Object*

---

**Description**

This method function extracts the first element of the `Dimnames` attribute, which contains the column names, for each block diagonal element in the matrix represented by `object`.

**Usage**

```
S3 method for class 'pdBlocked'
Names(object, asList, ...)
```

**Arguments**

- |        |                                                                                                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>pdBlocked</code> representing a positive-definite matrix with block diagonal structure                                                  |
| asList | a logical value. If TRUE a list with the names for each block diagonal element is returned. If FALSE a character vector with all column names is returned. Defaults to FALSE. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                     |

**Value**

if `asList` is FALSE, a character vector with column names of the matrix represented by `object`; otherwise, if `asList` is TRUE, a list with components given by the column names of the individual block diagonal elements in the matrix represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

pd1 <- pdBlocked(list(~Sex - 1, ~age - 1), data = Orthodont)
Names(pd1)
```

**Names.pdMat***Names of a pdMat Object*

## Description

This method function returns the first element of the `Dimnames` attribute of `object`, which contains the column names of the matrix represented by `object`.

## Usage

```
S3 method for class 'pdMat'
Names(object, ...)
S3 replacement method for class 'pdMat'
Names(object, ...) <- value
```

## Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>pdMat</code> , representing a positive-definite matrix.                                                                                                                                                                                                                                                              |
| <code>value</code>  | a character vector with the replacement values for the column and row names of the matrix represented by <code>object</code> . It must have length equal to the dimension of the matrix represented by <code>object</code> and, if names have been previously assigned to <code>object</code> , it must correspond to a permutation of the original names. |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                  |

## Value

if `object` has a `Dimnames` attribute then the first element of this attribute is returned; otherwise `NULL`.

## SIDE EFFECTS

On the left side of an assignment, sets the `Dimnames` attribute of `object` to `list(value, value)`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Names(pd1)
```

---

Names.reStruct      *Names of an reStruct Object*

---

## Description

This method function extracts the column names of each of the positive-definite matrices represented the pdMat elements of object.

## Usage

```
S3 method for class 'reStruct'
Names(object, ...)
S3 replacement method for class 'reStruct'
Names(object, ...) <- value
```

## Arguments

- object      an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of pdMat objects.  
value      a list of character vectors with the replacement values for the names of the individual pdMat objects that form `object`. It must have the same length as `object`.  
...      some methods for this generic require additional arguments. None are used in this method.

## Value

a list containing the column names of each of the positive-definite matrices represented by the pdMat elements of `object`.

## SIDE EFFECTS

On the left side of an assignment, sets the Names of the pdMat elements of `object` to the corresponding element of `value`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
Names(rs1)
```

`needUpdate`

*Check if Update is Needed*

## Description

This function is generic; method functions can be written to handle specific classes of objects. By default, it tries to extract a `needUpdate` attribute of object. If this is NULL or FALSE it returns FALSE; else it returns TRUE. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

## Usage

```
needUpdate(object)
```

## Arguments

|        |            |
|--------|------------|
| object | any object |
|--------|------------|

## Value

a logical value indicating whether object needs to be updated.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[needUpdate.modelStruct](#)

## Examples

```
vf1 <- varExp()
vf1 <- Initialize(vf1, data = Orthodont)
needUpdate(vf1)
```

`needUpdate.modelStruct`

*Check if a modelStruct Object Needs Updating*

## Description

This method function checks if any of the elements of object needs to be updated. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

## Usage

```
S3 method for class 'modelStruct'
needUpdate(object)
```

**Arguments**

**object** an object inheriting from class `modelStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects.

**Value**

a logical value indicating whether any element of `object` needs to be updated.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**See Also**

[needUpdate](#)

**Examples**

```
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
 varStruct = varPower(form = ~age))
needUpdate(lms1)
```

---

Nitrendipene

*Assay of nitrendipene*

---

**Description**

The Nitrendipene data frame has 89 rows and 4 columns.

**Format**

This data frame contains the following columns:

**activity** a numeric vector

**NIF** a numeric vector

**Tissue** an ordered factor with levels 2 < 1 < 3 < 4

**log.NIF** a numeric vector

**Source**

Bates, D. M. and Watts, D. G. (1988), *Nonlinear Regression Analysis and Its Applications*, Wiley, New York.

---

**nlme***Nonlinear Mixed-Effects Models*

---

**Description**

This generic function fits a nonlinear mixed-effects model in the formulation described in Lindstrom and Bates (1990) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
nlme(model, data, fixed, random, groups, start, correlation, weights,
 subset, method, na.action, naPattern, control, verbose)
```

**Arguments**

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>model</b>  | a nonlinear model formula, with the response on the left of a <code>~</code> operator and an expression involving parameters and covariates on the right, or an <code>nlsList</code> object. If <code>data</code> is given, all names used in the formula should be defined as parameters or variables in the data frame. The method function <code>nlme.nlsList</code> is documented separately.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>data</b>   | an optional data frame containing the variables named in <code>model</code> , <code>fixed</code> , <code>random</code> , <code>correlation</code> , <code>weights</code> , <code>subset</code> , and <code>naPattern</code> . By default the variables are taken from the environment from which <code>nlme</code> is called.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>fixed</b>  | a two-sided linear formula of the form <code>f1+...+fn~x1+...+xm</code> , or a list of two-sided formulas of the form <code>f1~x1+...+xm</code> , with possibly different models for different parameters. The <code>f1, ..., fn</code> are the names of parameters included on the right hand side of <code>model</code> and the <code>x1+...+xm</code> expressions define linear models for these parameters (when the left hand side of the formula contains several parameters, they all are assumed to follow the same linear model, described by the right hand side expression). A <code>1</code> on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>random</b> | optionally, any of the following: (i) a two-sided formula of the form <code>r1+...+rn~x1+...+xm   g1/.../gQ</code> , with <code>r1, ..., rn</code> naming parameters included on the right hand side of <code>model</code> , <code>x1+...+xm</code> specifying the random-effects model for these parameters and <code>g1/.../gQ</code> the grouping structure ( <code>Q</code> may be equal to 1, in which case no <code>/</code> is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a two-sided formula of the form <code>r1+...+rn~x1+...+xm</code> , a list of two-sided formulas of the form <code>r1~x1+...+xm</code> , with possibly different random-effects models for different parameters, a <code>pdMat</code> object with a two-sided formula, or list of two-sided formulas (i.e. a non-NULL value for <code>formula(random)</code> ), or a list of <code>pdMat</code> objects with two-sided formulas, or lists of two-sided formulas. In this case, the grouping structure formula will be given in <code>groups</code> , or derived from the data used to fit the nonlinear mixed-effects model, which should inherit from class <code>groupedData</code> ; (iii) a named list of formulas, lists of formulas, or <code>pdMat</code> objects as in (ii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (iv) an <code>reStruct</code> object. See the documentation on <code>pdClasses</code> for a description of the available <code>pdMat</code> classes. Defaults to <code>fixed</code> , resulting in all fixed effects having also random effects. |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| groups      | an optional one-sided formula of the form $\sim g1$ (single level of nesting) or $\sim g1/\dots/gQ$ (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. $g1, \dots, gQ$ must evaluate to factors in data. The order of nesting, when multiple levels are present, is taken from left to right (i.e. $g1$ is the first level, $g2$ the second, etc.).                                                                                                                                                                                                                                                                                                                                                                                                                   |
| start       | an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component <code>fixed</code> , given by the vector. The <code>fixed</code> component is required, unless the model function inherits from class <code>selfStart</code> , in which case initial values will be derived from a call to <code>nlsList</code> . An optional <code>random</code> component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level. |
| correlation | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| weights     | an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.                                                                                                                                                                                                                                                                                                                                                                         |
| subset      | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| method      | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| na.action   | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlme</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| naPattern   | an expression or formula object, specifying which returned values are to be regarded as missing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| control     | a list of control values for the estimation algorithm to replace the default values returned by the function <code>nlmeControl</code> . Defaults to an empty list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| verbose     | an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### Value

an object of class `nlme` representing the nonlinear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `nlmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

### Note

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

The model formulation and computational methods are described in Lindstrom, M.J. and Bates, D.M. (1990). The variance-covariance parametrizations are described in Pinheiro, J.C. and Bates., D.M. (1996). The different correlation structures available for the correlation argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littel, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). The use of variance functions for linear and nonlinear mixed effects models is presented in detail in Davidian, M. and Giltinan, D.M. (1995).

**Examples**

```
fm1 <- nlme(height ~ SSasymp(age, Asym, R0, lrc),
 data = Loblolly,
 fixed = Asym + R0 + lrc ~ 1,
 random = Asym ~ 1,
 start = c(Asym = 103, R0 = -8.5, lrc = -3.3))
summary(fm1)
fm2 <- update(fm1, random = pdDiag(Asym + lrc ~ 1))
summary(fm2)
```

---

nlme.nlsListNLME fit from nlsList Object

---

**Description**

If the random effects names defined in `random` are a subset of the `lmlist` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain `fixed` are passed as the `fixed` and `data` arguments to `nlme.formula`, together with any other additional arguments in the function call. See the documentation on `nlme.formula` for a description of that function.

**Usage**

```
S3 method for class 'nlsList'
nlme(model, data, fixed, random, groups, start, correlation, weights,
subset, method, na.action, naPattern, control, verbose)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model</code>       | an object inheriting from class <code>nlsList</code> , representing a list of <code>nls</code> fits with a common model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>data</code>        | this argument is included for consistency with the generic function. It is ignored in this method function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>fixed</code>       | this argument is included for consistency with the generic function. It is ignored in this method function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>random</code>      | an optional one-sided linear formula with no conditioning expression, or a <code>pdMat</code> object with a <code>formula</code> attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of <code>formula(fixed)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>groups</code>      | an optional one-sided formula of the form <code>~g1</code> (single level of nesting) or <code>~g1/.../gQ</code> (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. <code>g1, ..., gQ</code> must evaluate to factors in <code>data</code> . The order of nesting, when multiple levels are present, is taken from left to right (i.e. <code>g1</code> is the first level, <code>g2</code> the second, etc.).                                                                                                                                                                                                                                                                                                                                                                       |
| <code>start</code>       | an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component <code>fixed</code> , given by the vector. The <code>fixed</code> component is required, unless the <code>model</code> function inherits from class <code>selfStart</code> , in which case initial values will be derived from a call to <code>nlsList</code> . An optional <code>random</code> component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level. |
| <code>correlation</code> | an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|           |                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| weights   | an optional varFunc object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to varFixed, corresponding to fixed variance weights. See the documentation on varClasses for a description of the available varFunc classes. Defaults to NULL, corresponding to homoscedastic within-group errors. |
| subset    | an optional expression indicating the subset of the rows of data that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                                                                    |
| method    | a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "ML".                                                                                                                                                                                                                          |
| na.action | a function that indicates what should happen when the data contain NAs. The default action (na.fail) causes nlme to print an error message and terminate if there are any incomplete observations.                                                                                                                                                                              |
| naPattern | an expression or formula object, specifying which returned values are to be regarded as missing.                                                                                                                                                                                                                                                                                |
| control   | a list of control values for the estimation algorithm to replace the default values returned by the function nlmeControl. Defaults to an empty list.                                                                                                                                                                                                                            |
| verbose   | an optional logical value. If TRUE information on the evolution of the iterative algorithm is printed. Default is FALSE.                                                                                                                                                                                                                                                        |

### Value

an object of class nlme representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `nlmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

The computational methods follow on the general framework of Lindstrom, M.J. and Bates, D.M. (1988). The model formulation is described in Laird, N.M. and Ware, J.H. (1982). The variance-covariance parametrizations are described in <Pinheiro, J.C. and Bates., D.M. (1996). The different correlation structures available for the correlation argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littel, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). The use of variance functions for linear and nonlinear mixed effects models is presented in detail in Davidian, M. and Giltinan, D.M. (1995).

## Examples

```
fm1 <- nlsList(SSasymp, data = Loblolly)
fm2 <- nlme(fm1, random = Asym ~ 1)
summary(fm1)
summary(fm2)
```

**nlmeControl**

*Control Values for nlme Fit*

## Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `nlme` function.

## Usage

```
nlmeControl(maxIter, pnlsMaxIter, msMaxIter, minScale,
 tolerance, niterEM, pnlsTol, msTol, msScale,
 returnObject, msVerbose, gradHess, apVar, .relStep,
 nlmStepMax = 100.0, minAbsParApVar = 0.05,
 opt = c("nlminb", "nlm"), natural = TRUE, ...)
```

## Arguments

|                          |                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>maxIter</code>     | maximum number of iterations for the <code>nlme</code> optimization algorithm. Default is 50.                                                         |
| <code>pnlsMaxIter</code> | maximum number of iterations for the PNLS optimization step inside the <code>nlme</code> optimization. Default is 7.                                  |
| <code>msMaxIter</code>   | maximum number of iterations for the <code>nlm</code> optimization step inside the <code>nlme</code> optimization. Default is 50.                     |
| <code>minScale</code>    | minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the PNLS step. Default 0.001.                 |
| <code>tolerance</code>   | tolerance for the convergence criterion in the <code>nlme</code> algorithm. Default is 1e-6.                                                          |
| <code>niterEM</code>     | number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25. |
| <code>pnlsTol</code>     | tolerance for the convergence criterion in PNLS step. Default is 1e-3.                                                                                |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>msTol</code>          | tolerance for the convergence criterion in <code>nlm</code> , passed as the <code>rel.tolerance</code> argument to the function (see documentation on <code>nlm</code> ). Default is 1e-7.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>msScale</code>        | scale function passed as the <code>scale</code> argument to the <code>nlm</code> function (see documentation on that function). Default is <code>lmeScale</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>returnObject</code>   | a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>msVerbose</code>      | a logical value passed as the <code>trace</code> argument to <code>nlm</code> (see documentation on that function). Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>gradHess</code>       | a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the <code>nlm</code> optimization. This option is only available when the correlation structure ( <code>corStruct</code> ) and the variance function structure ( <code>varFunc</code> ) have no "varying" parameters and the <code>pdMat</code> classes used in the random effects structure are <code>pdSymm</code> (general positive-definite), <code>pdDiag</code> (diagonal), <code>pdIdent</code> (multiple of the identity), or <code>pdCompSymm</code> (compound symmetry). Default is TRUE. |
| <code>apVar</code>          | a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>.relStep</code>       | relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>nlmStepMax</code>     | stepmax value to be passed to <code>nlm</code> . See <code>nlm</code> for details. Default is 100.0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>minAbsParApVar</code> | numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>opt</code>            | the optimizer to be used, either " <code>link{nlminb}</code> "(the default) or " <code>link{nlm}</code> ".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>natural</code>        | a logical value indicating whether the <code>pdNatural</code> parametrization should be used for general positive-definite matrices ( <code>pdSymm</code> ) in <code>reStruct</code> , when the approximate covariance matrix of the estimators is calculated. Default is TRUE.                                                                                                                                                                                                                                                                                                                                                         |
| <code>...</code>            | Further named control arguments to be passed to <code>nlminb</code> , where used ( <code>eval.max</code> and those from <code>abs.tol</code> down).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### Value

a list with components for each of the possible arguments.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`nlme`, `nlm`, `optim`, `nlmeStruct`

### Examples

```
decrease the maximum number iterations in the ms call and
request that information on the evolution of the ms iterations be printed
nlmeControl(msMaxIter = 20, msVerbose = TRUE)
```

### Description

An object returned by the `nlme` function, inheriting from class `nlme`, also inheriting from class `lme`, and representing a fitted nonlinear mixed-effects model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `fixed.effects`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `pairs`, `plot`, `predict`, `print`, `random.effects`, `residuals`, `summary`, and `update`.

### Value

The following components must be included in a legitimate `nlme` object.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>apVar</code>        | an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>nlme</code> , this component is equal to <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>call</code>         | a list containing an image of the <code>nlme</code> call that produced the object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>coefficients</code> | a list with two components, <code>fixed</code> and <code>random</code> , where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the <code>random</code> list, the columns refer to the random effects and the rows to the groups.                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>contrasts</code>    | a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the <code>nlme</code> model, this component will be an empty list.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>dims</code>         | a list with basic dimensions used in the <code>nlme</code> fit, including the components <code>N</code> - the number of observations in the data, <code>Q</code> - the number of grouping levels, <code>qvec</code> - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), <code>ngrps</code> - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and <code>ncol</code> - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one). |
| <code>fitted</code>       | a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>fixDF</code>        | a list with components <code>X</code> and <code>terms</code> specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>groups</code>       | a data frame with the grouping factors as columns. The grouping level increases from left to right.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>logLik</code>       | the (restricted) log-likelihood at convergence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>map</code>          | a list with components <code>fmap</code> , <code>rmap</code> , <code>rmapRel</code> , and <code>bmap</code> , specifying various mappings for the fixed and random effects, used to generate predictions from the fitted object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                    |                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>method</b>      | the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.                                                                                        |
| <b>modelStruct</b> | an object inheriting from class <i>nlmeStruct</i> , representing a list of mixed-effects model components, such as <i>reStruct</i> , <i>corStruct</i> , and <i>varFunc</i> objects.            |
| <b>numIter</b>     | the number of iterations used in the iterative algorithm.                                                                                                                                      |
| <b>residuals</b>   | a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping. |
| <b>sigma</b>       | the estimated within-group error standard deviation.                                                                                                                                           |
| <b>varFix</b>      | an approximate covariance matrix of the fixed effects estimates.                                                                                                                               |

*nlmeStruct*

*Nonlinear Mixed-Effects Structure*

**Description**

A nonlinear mixed-effects structure is a list of model components representing different sets of parameters in the nonlinear mixed-effects model. An *nlmeStruct* list must contain at least a *reStruct* object, but may also contain *corStruct* and *varFunc* objects. NULL arguments are not included in the *nlmeStruct* list.

**Usage**

```
nlmeStruct(reStruct, corStruct, varStruct)
```

**Arguments**

|                  |                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------|
| <b>reStruct</b>  | a <i>reStruct</i> representing a random effects structure.                                      |
| <b>corStruct</b> | an optional <i>corStruct</i> object, representing a correlation structure. Default is NULL.     |
| <b>varStruct</b> | an optional <i>varFunc</i> object, representing a variance function structure. Default is NULL. |

**Value**

a list of model components determining the parameters to be estimated for the associated nonlinear mixed-effects model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
n1ms1 <- nlmeStruct(reStruct(~age), corAR1(), varPower())
```

---

nlsList

*List of nls Objects with a Common Model*

---

**Description**

Data is partitioned according to the levels of the grouping factor defined in `model` and individual `nls` fits are obtained for each data partition, using the model defined in `model1`.

**Usage**

```
nlsList(model, data, start, control, level, subset, na.action, pool)
S3 method for class 'nlsList'
update(object, model., ..., evaluate = TRUE)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | an object inheriting from class <code>nlsList</code> , representing a list of fitted <code>nls</code> objects.                                                                                                                                                                                                                                   |
| <code>model</code>     | either a nonlinear model formula, with the response on the left of a <code>~</code> operator and an expression involving parameters, covariates, and a grouping factor separated by the <code> </code> operator on the right, or a <code>selfStart</code> function. The method function <code>nlsList.selfStart</code> is documented separately. |
| <code>model.</code>    | Changes to the model – see <code>update.formula</code> for details.                                                                                                                                                                                                                                                                              |
| <code>data</code>      | a data frame in which to interpret the variables named in <code>model</code> .                                                                                                                                                                                                                                                                   |
| <code>start</code>     | an optional named list with initial values for the parameters to be estimated in <code>model</code> . It is passed as the <code>start</code> argument to each <code>nls</code> call and is required when the nonlinear function in <code>model</code> does not inherit from class <code>selfStart</code> .                                       |
| <code>control</code>   | a list of control values passed as the <code>control</code> argument to <code>nls</code> . Defaults to an empty list.                                                                                                                                                                                                                            |
| <code>level</code>     | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.                                                                                                                                                                                                                             |
| <code>subset</code>    | an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.                        |
| <code>na.action</code> | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlsList</code> to print an error message and terminate if there are any incomplete observations.                                                                                                                |
| <code>pool</code>      | an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for <code>pool</code> in calculations of standard deviations or standard errors for summaries.                                                                                                                               |
| <code>...</code>       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                        |
| <code>evaluate</code>  | If <code>TRUE</code> evaluate the new call else return the call.                                                                                                                                                                                                                                                                                 |

**Value**

a list of `nls` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `nlsList` object.

**See Also**

`nls`, `nlme.nlsList`, `nlsList.selfStart`, `summary.nlsList`

**Examples**

```
fm1 <- nlsList(uptake ~ SSasympOff(conc, Asym, lrc, c0),
 data = CO2, start = c(Asym = 30, lrc = -4.5, c0 = 52))
summary(fm1)
```

`nlsList.selfStart`

*nlsList Fit from a selfStart Function*

**Description**

The response variable and primary covariate in `formula(data)` are used together with `model` to construct the nonlinear model formula. This is used in the `nls` calls and, because a `selfStarting` model function can calculate initial estimates for its parameters from the data, no starting estimates need to be provided.

**Usage**

```
S3 method for class 'selfStart'
nlsList(model, data, start, control, level, subset, na.action, pool)
```

**Arguments**

|                      |                                                                                                                                                                                                                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>model</code>   | a <code>selfStart</code> model function, which calculates initial estimates for the model parameters from <code>data</code> .                                                                                                                                                                                             |
| <code>data</code>    | a data frame in which to interpret the variables in <code>model</code> . Because no grouping factor can be specified in <code>model</code> , <code>data</code> must inherit from class <code>groupedData</code> .                                                                                                         |
| <code>start</code>   | an optional named list with initial values for the parameters to be estimated in <code>model</code> . It is passed as the <code>start</code> argument to each <code>nls</code> call and is required when the nonlinear function in <code>model</code> does not inherit from class <code>selfStart</code> .                |
| <code>control</code> | a list of control values passed as the <code>control</code> argument to <code>nls</code> . Defaults to an empty list.                                                                                                                                                                                                     |
| <code>level</code>   | an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.                                                                                                                                                                                                      |
| <code>subset</code>  | an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default. |

|           |                                                                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| na.action | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlsList</code> to print an error message and terminate if there are any incomplete observations. |
| pool      | an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for <code>pool</code> in calculations of standard deviations or standard errors for summaries.                |

**Value**

a list of `nls` objects with as many components as the number of groups defined by the grouping factor. A `NULL` value is assigned to the components corresponding to clusters for which the `nls` algorithm failed to converge. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `nlsList` object.

**See Also**

`selfStart`, `groupedData`, `nls`, `nlsList`, `nlme.nlsList`, `nlsList.formula`

**Examples**

```
fm1 <- nlsList(SSasympOff, CO2)
summary(fm1)
```

**Description**

The `Oats` data frame has 72 rows and 4 columns.

**Format**

This data frame contains the following columns:

- Block** an ordered factor with levels VI < V < III < IV < II < I
- Variety** a factor with levels Golden Rain Marvellous Victory
- nitro** a numeric vector
- yield** a numeric vector

**Details**

These data have been introduced by Yates (1935) as an example of a split-plot design. The treatment structure used in the experiment was a  $3 \times 4$  full factorial, with three varieties of oats and four concentrations of nitrogen. The experimental units were arranged into six blocks, each with three whole-plots subdivided into four subplots. The varieties of oats were assigned randomly to the whole-plots and the concentrations of nitrogen to the subplots. All four concentrations of nitrogen were used on each whole-plot.

Orthodont

*Growth curve data on an orthodontic measurement*

### Description

The Orthodont data frame has 108 rows and 4 columns of the change in an orthodontic measurement over time for several young subjects.

### Format

This data frame contains the following columns:

**distance** a numeric vector of distances from the pituitary to the pterygomaxillary fissure (mm). These distances are measured on x-ray images of the skull.

**age** a numeric vector of ages of the subject (yr).

**Subject** an ordered factor indicating the subject on which the measurement was made. The levels are labelled M01 to M16 for the males and F01 to F13 for the females. The ordering is by increasing average distance within sex.

**Sex** a factor with levels Male and Female

### Details

Investigators at the University of North Carolina Dental School followed the growth of 27 children (16 males, 11 females) from age 8 until age 14. Every two years they measured the distance between the pituitary and the pterygomaxillary fissure, two points that are easily identified on x-ray exposures of the side of the head.

**Ovary***Counts of Ovarian Follicles*

---

**Description**

The Ovary data frame has 308 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Mare** an ordered factor indicating the mare on which the measurement is made.

**Time** time in the estrus cycle. The data were recorded daily from 3 days before ovulation until 3 days after the next ovulation. The measurement times for each mare are scaled so that the ovulations for each mare occur at times 0 and 1.

**follicles** the number of ovarian follicles greater than 10 mm in diameter.

**Details**

Pierson and Ginther (1987) report on a study of the number of large ovarian follicles detected in different mares at several times in their estrus cycles.

---

**Oxboys***Heights of Boys in Oxford*

---

**Description**

The Oxboys data frame has 234 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Subject** an ordered factor giving a unique identifier for each boy in the experiment

**age** a numeric vector giving the standardized age (dimensionless)

**height** a numeric vector giving the height of the boy (cm)

**Occasion** an ordered factor - the result of converting age from a continuous variable to a count so these slightly unbalanced data can be analyzed as balanced.

## Details

These data are described in Goldstein (1987) as data on the height of a selection of boys from Oxford, England versus a standardized age.

## Source

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York. (Appendix A.19)

## Description

The Oxide data frame has 72 rows and 5 columns.

## Format

This data frame contains the following columns:

**Source** a factor with levels 1 and 2

**Lot** a factor giving a unique identifier for each lot.

**Wafer** a factor giving a unique identifier for each wafer within a lot.

**Site** a factor with levels 1, 2, and 3

**Thickness** a numeric vector giving the thickness of the oxide layer.

## Details

These data are described in Littell et al. (1996, p. 155) as coming “from a passive data collection study in the semiconductor industry where the objective is to estimate the variance components to determine the assignable causes of the observed variability.” The observed response is the thickness of the oxide layer on silicon wafers, measured at three different sites of each of three wafers selected from each of eight lots sampled from the population of lots.

**pairs.compareFits***Pairs Plot of compareFits Object*

---

## Description

Scatter plots of the values being compared are generated for each pair of coefficients in *x*. Different symbols (colors) are used for each object being compared and values corresponding to the same group are joined by a line, to facilitate comparison of fits. If only two coefficients are present, the *trellis* function *xyplot* is used; otherwise the *trellis* function *splom* is used.

## Usage

```
S3 method for class 'compareFits'
pairs(x, subset, key, ...)
```

## Arguments

- |               |                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>x</i>      | an object of class <i>compareFits</i> .                                                                                                                                                                                                                                                                                                                                       |
| <i>subset</i> | an optional logical or integer vector specifying which rows of <i>x</i> should be used in the plots. If missing, all rows are used.                                                                                                                                                                                                                                           |
| <i>key</i>    | an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If FALSE, no legend is included. If given as a list, <i>key</i> is passed down as an argument to the <i>trellis</i> function generating the plots ( <i>splom</i> or <i>xyplot</i> ). Defaults to TRUE. |
| ...           | optional arguments passed down to the <i>trellis</i> function generating the plots.                                                                                                                                                                                                                                                                                           |

## Value

Pairwise scatter plots of the values being compared, with different symbols (colors) used for each object under comparison.

pairs(compareFits(coef(fm1), coef(fm2)))
```

---

**pairs.lme***Pairs Plot of an lme Object*

---

**Description**

Diagnostic plots for the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a `|` operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function `xypplot` is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function `splom` is used).

**Usage**

```
S3 method for class 'lme'
pairs(x, form, label, id, idLabels, grid, ...)
```

**Arguments**

- |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>        | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>form</code>     | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> , and to the left of the <code> </code> operator, must evaluate to a data frame with at least two columns. Default is <code>~ coef(.)</code> , corresponding to a pairs plot of the coefficients evaluated at the innermost level of nesting. |
| <code>label</code>    | an optional character vector of labels for the variables in the pairs plot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>id</code>       | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the $1 - \text{value}$ percentile of the appropriate chi-square distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.                                                                                                                         |
| <code>idLabels</code> | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor.                                                                                                                                                                                                                                                                                                                                              |
| <code>grid</code>     | an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>...</code>      | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Value**

a diagnostic Trellis plot.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lme](#), [pairs.compareFits](#), [pairs.lmList](#), [xyplot](#), [splom](#)

**Examples**

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
scatter plot of coefficients by gender, identifying unusual subjects
pairs(fm1, ~coef(.), augFrame = TRUE) | Sex, id = 0.1, adj = -0.5)
scatter plot of estimated random effects
Not run:
pairs(fm1, ~ranef(.))

End(Not run)
```

**pairs.lmList**

*Pairs Plot of an lmList Object*

**Description**

Diagnostic plots for the linear model fits corresponding to the `x` components are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a `|` operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function `xyplot` is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function `splom` is used).

**Usage**

```
S3 method for class 'lmList'
pairs(x, form, label, id, idLabels, grid, ...)
```

**Arguments**

- |                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>form</code> | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> , and to the left of the <code> </code> operator, must evaluate to a data frame with at least two columns. Default is <code>~ coef(.)</code> , corresponding to a pairs plot of the coefficients of <code>x</code> . |

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| label    | an optional character vector of labels for the variables in the pairs plot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| id       | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the $1 - value$ percentile of the appropriate chi-square distribution are identified in the plot using idLabels. If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified. |
| idLabels | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to id. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor.                                                                                                                                                                                                               |
| grid     | an optional logical value indicating whether a grid should be added to plot. Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ...      | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### Value

a diagnostic Trellis plot.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
scatter plot of coefficients by gender, identifying unusual subjects
pairs(fm1, ~coef(.) | Sex, id = 0.1, adj = -0.5)
scatter plot of estimated random effects
Not run:
pairs(fm1, ~ranef(.))

End(Not run)
```

### Description

The PBG data frame has 60 rows and 5 columns.

## Format

This data frame contains the following columns:

**deltaBP** a numeric vector

**dose** a numeric vector

**Run** an ordered factor with levels T5 < T4 < T3 < T2 < T1 < P5 < P3 < P2 < P4 < P1

**Treatment** a factor with levels MDL 72222 Placebo

**Rabbit** an ordered factor with levels 5 < 3 < 2 < 4 < 1

## Details

Data on an experiment to examine the effect of a antagonist MDL 72222 on the change in blood pressure experienced with increasing dosage of phenylbiguanide are described in Ludbrook (1994) and analyzed in Venables and Ripley (2002, section 10.3). Each of five rabbits was exposed to increasing doses of phenylbiguanide after having either a placebo or the HD5-antagonist MDL 72222 administered.

## Description

This function is a constructor for the pdBlocked class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual pdMat object. When value is numeric(0), a list of uninitialized pdMat objects, a list of one-sided formulas, or a list of vectors of character strings, object is returned as an uninitialized pdBlocked object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is a list of initialized pdMat objects, object will be constructed from the list obtained by applying as.matrix to each of the pdMat elements of value. Finally, if value is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

## Usage

```
pdBlocked(value, form, nam, data, pdClass)
```

**Arguments**

|                |                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>value</b>   | an optional list with elements to be used as the value argument to other pdMat constructors. These include: pdMat objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to numeric(0), corresponding to an uninitialized object. |
| <b>form</b>    | an optional list of one-sided linear formulas specifying the row/column names for the block-diagonal elements of the matrix represented by object. Because factors may be present in form, the formulas needs to be evaluated on a data.frame to resolve the names they define. This argument is ignored when value is a list of one-sided formulas. Defaults to NULL.                                |
| <b>nam</b>     | an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by object. Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when value is a list of vector of character strings. Defaults to NULL.            |
| <b>data</b>    | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on any factors appearing in the formulas. Defaults to the parent frame from which the function was called.                           |
| <b>pdClass</b> | an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".                                                                    |

**Value**

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

**pdClasses***Positive-Definite Matrix Classes*

---

**Description**

Standard classes of positive-definite matrices (`pdMat`) structures available in the `nlme` library.

**Value**

Available standard classes:

|                         |                                                                                                                                                                                                                                        |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pdSymm</code>     | general positive-definite matrix, with no additional structure                                                                                                                                                                         |
| <code>pdLogChol</code>  | general positive-definite matrix, with no additional structure, using a log-Cholesky parameterization                                                                                                                                  |
| <code>pdDiag</code>     | diagonal                                                                                                                                                                                                                               |
| <code>pdIdent</code>    | multiple of an identity                                                                                                                                                                                                                |
| <code>pdCompSymm</code> | compound symmetry structure (constant diagonal and constant off-diagonal elements)                                                                                                                                                     |
| <code>pdBlocked</code>  | block-diagonal matrix, with diagonal blocks of any "atomic" <code>pdMat</code> class                                                                                                                                                   |
| <code>pdNatural</code>  | general positive-definite matrix in natural parametrization (i.e. parametrized in terms of standard deviations and correlations). The underlying coefficients are not unrestricted, so this class should NOT be used for optimization. |

**Note**

Users may define their own `pdMat` classes by specifying a constructor function and, at a minimum, methods for the functions `pdConstruct`, `pdMatrix` and `coef`. For examples of these functions, see the methods for classes `pdSymm` and `pdDiag`.

pdCompSymm

*Positive-Definite Matrix with Compound Symmetry Structure*

## Description

This function is a constructor for the *pdCompSymm* class, representing a positive-definite matrix with compound symmetry structure (constant diagonal and constant off-diagonal elements). The underlying matrix is represented by 2 unrestricted parameters. When *value* is *numeric(0)*, an uninitialized *pdMat* object, a one-sided formula, or a vector of character strings, *object* is returned as an uninitialized *pdCompSymm* object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the *coef* or *matrix* replacement functions. If *value* is an initialized *pdMat* object, *object* will be constructed from *as.matrix(value)*. Finally, if *value* is a numeric vector of length 2, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

## Usage

```
pdCompSymm(value, form, nam, data)
```

## Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>value</i> | an optional initialization value, which can be any of the following: a <i>pdMat</i> object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector of length 2. Defaults to <i>numeric(0)</i> , corresponding to an uninitialized object.                                                                  |
| <i>form</i>  | an optional one-sided linear formula specifying the row/column names for the matrix represented by <i>object</i> . Because factors may be present in <i>form</i> , the formula needs to be evaluated on a <i>data.frame</i> to resolve the names it defines. This argument is ignored when <i>value</i> is a one-sided formula. Defaults to <i>NULL</i> .                                      |
| <i>nam</i>   | an optional vector of character strings specifying the row/column names for the matrix represented by <i>object</i> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <i>value</i> is a vector of character strings. Defaults to <i>NULL</i> .                                                  |
| <i>data</i>  | an optional data frame in which to evaluate the variables named in <i>value</i> and <i>form</i> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <i>NULL</i> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

## Value

a *pdCompSymm* object representing a positive-definite matrix with compound symmetry structure, also inheriting from class *pdMat*.

pdConstruct

*Construct pdMat Objects*

---

**Description**

This function is an alternative constructor for the `pdMat` class associated with `object` and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the `pdMat` class of `object`.

**Usage**

```
pdConstruct(object, value, form, nam, data, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>pdMat</code> , representing a positive definite matrix.                                                                                                                                                                                                                                                                                                                    |
| <code>value</code>  | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.                                                                      |
| <code>form</code>   | an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .                          |
| <code>nam</code>    | an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .                                                  |
| <code>data</code>   | an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| <code>...</code>    | optional arguments for some methods.                                                                                                                                                                                                                                                                                                                                                                             |

**Value**

a `pdMat` object representing a positive-definite matrix, inheriting from the same classes as `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```
pd1 <- pdSymm()
pdConstruct(pd1, diag(1:4))
```

**pdConstruct.pdBlocked** *Construct pdBlocked Objects*

**Description**

This function give an alternative constructor for the `pdBlocked` class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual `pdMat` object. When `value` is `numeric(0)`, a list of uninitialized `pdMat` objects, a list of one-sided formulas, or a list of vectors of character strings, `object` is returned as an uninitialized `pdBlocked` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is a list of initialized `pdMat` objects, `object` will be constructed from the list obtained by applying `as.matrix` to each of the `pdMat` elements of `value`. Finally, if `value` is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

**Usage**

```
S3 method for class 'pdBlocked'
pdConstruct(object, value, form, nam, data, pdClass,
...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>pdBlocked</code> , representing a positive definite block-diagonal matrix.                                                                                                                                                                                                                                                                                                                                           |
| <code>value</code>  | an optional list with elements to be used as the <code>value</code> argument to other <code>pdMat</code> constructors. These include: <code>pdMat</code> objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object. |
| <code>form</code>   | an optional list of one-sided linear formula specifying the row/column names for the block-diagonal elements of the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formulas needs to be evaluated on a <code>data.frame</code> to resolve the names they defines. This argument is ignored when <code>value</code> is a list of one-sided formulas. Defaults to <code>NULL</code> .                 |
| <code>nam</code>    | an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by <code>object</code> . Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when <code>value</code> is a list of vector of character strings. Defaults to <code>NULL</code> .                        |

|         |                                                                                                                                                                                                                                                                                                                                                                         |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data    | an optional data frame in which to evaluate the variables named in value and form. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| pdClass | an optional vector of character strings naming the pdMat classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when value is missing, or its elements are not pdMat objects. Defaults to "pdSymm".                                      |
| ...     | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                               |

**Value**

a pdBlocked object representing a positive-definite block-diagonal matrix, also inheriting from class pdMat.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

[as.matrix.pdMat](#), [coef.pdMat](#), [pdBlocked](#), [pdClasses](#), [pdConstruct](#), [matrix<- .pdMat](#)

**Examples**

```
pd1 <- pdBlocked(list(c("A","B"), c("a1", "a2", "a3")))
pdConstruct(pd1, list(diag(1:2), diag(c(0.1, 0.2, 0.3))))
```

pdDiag

*Diagonal Positive-Definite Matrix*

**Description**

This function is a constructor for the pdDiag class, representing a diagonal positive-definite matrix. If the matrix associated with object is of dimension  $n$ , it is represented by  $n$  unrestricted parameters, given by the logarithm of the square-root of the diagonal values. When value is numeric(0), an uninitialized pdMat object, a one-sided formula, or a vector of character strings, object is returned as an uninitialized pdDiag object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the coef or matrix replacement functions. If value is an initialized pdMat object, object will be constructed from [as.matrix\(value\)](#). Finally, if value is a numeric vector, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

**Usage**

```
pdDiag(value, form, nam, data)
```

**Arguments**

|              |                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>value</b> | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector of length equal to the dimension of the underlying positive-definite matrix. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object. |
| <b>form</b>  | an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .                                 |
| <b>nam</b>   | an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .                                                         |
| <b>data</b>  | an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.        |

**Value**

a `pdDiag` object representing a diagonal positive-definite matrix, also inheriting from class `pdMat`.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

[as.matrix.pdMat](#), [coef.pdMat](#), [pdClasses](#), [matrix<- .pdMat](#)

**Examples**

```
pd1 <- pdDiag(diag(1:3), nam = c("A", "B", "C"))
pd1
```

**Description**

A square-root factor of the positive-definite matrix represented by `object` is obtained. Letting  $\Sigma$  denote a positive-definite matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This function extracts  $L$ .

**Usage**

```
pdFactor(object)
```

**Arguments**

object           an object inheriting from class pdMat, representing a positive definite matrix, which must have been initialized (i.e. `length(coef(object)) > 0`).

**Value**

a vector with a square-root factor of the positive-definite matrix associated with object stacked column-wise.

**Note**

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `pdMatrix` function can be used to obtain square-root factors in matrix form.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**Examples**

```
pd1 <- pdCompSymm(4 * diag(3) + 1)
pdFactor(pd1)
```

---

`pdFactor.reStruct`      *Extract Square-Root Factor from Components of an reStruct Object*

---

**Description**

This method function extracts square-root factors of the positive-definite matrices corresponding to the pdMat elements of object.

**Usage**

```
S3 method for class 'reStruct'
pdFactor(object)
```

**Arguments**

object           an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of pdMat objects.

**Value**

a vector with square-root factors of the positive-definite matrices corresponding to the elements of object stacked column-wise.

**Note**

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `pdMatrix` function can be used to obtain square-root factors in matrix form.

```

**pdIdent**

*Multiple of the Identity Positive-Definite Matrix*

**Description**

This function is a constructor for the `pdIdent` class, representing a multiple of the identity positive-definite matrix. The matrix associated with object is represented by 1 unrestricted parameter, given by the logarithm of the square-root of the diagonal value. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdIdent` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric value, it is assumed to represent the unrestricted coefficient of the underlying positive-definite matrix.

**Usage**

```
pdIdent(value, form, nam, data)
```

### Arguments

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code> | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric value. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.                                                                                                  |
| <code>form</code>  | an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .                                                     |
| <code>nam</code>   | an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .                                                                             |
| <code>data</code>  | an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called. |

## Description

This function is a constructor for the *pdLogChol* class, representing a general positive-definite matrix. If the matrix associated with *object* is of dimension  $n$ , it is represented by  $n(n + 1)/2$  unrestricted parameters, using the log-Cholesky parametrization described in Pinheiro and Bates (1996). When *value* is *numeric(0)*, an uninitialized *pdMat* object, a one-sided formula, or a vector of character strings, *object* is returned as an uninitialized *pdLogChol* object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the *coef* or *matrix* replacement functions. If *value* is an initialized *pdMat* object, *object* will be constructed from *as.matrix(value)*. Finally, if *value* is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

## Usage

```
pdLogChol(value, form, nam, data)
```

## Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>value</i> | an optional initialization value, which can be any of the following: a <i>pdMat</i> object, a positive-definite matrix, a one-sided linear formula (with variables separated by $+$ ), a vector of character strings, or a numeric vector. Defaults to <i>numeric(0)</i> , corresponding to an uninitialized object.                                                                                          |
| <i>form</i>  | an optional one-sided linear formula specifying the row/column names for the matrix represented by <i>object</i> . Because factors may be present in <i>form</i> , the formula needs to be evaluated on a <i>data.frame</i> to resolve the names it defines. This argument is ignored when <i>value</i> is a one-sided formula. Defaults to <i>NULL</i> .                                                     |
| <i>nam</i>   | an optional vector of character strings specifying the row/column names for the matrix represented by <i>object</i> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <i>value</i> is a vector of character strings. Defaults to <i>NULL</i> .                                                                 |
| <i>data</i>  | an optional data frame in which to evaluate the variables named in <i>value</i> and <i>form</i> . It is used to obtain the levels for <i>factors</i> , which affect the dimensions and the row/column names of the underlying matrix. If <i>NULL</i> , no attempt is made to obtain information on <i>factors</i> appearing in the formulas. Defaults to the parent frame from which the function was called. |

## Value

a *pdLogChol* object representing a general positive-definite matrix, also inheriting from class *pdMat*.

pdMat

*Positive-Definite Matrix*

---

**Description**

This function gives an alternative way of constructing an object inheriting from the `pdMat` class named in `pdClass`, or from `data.class(object)` if `object` inherits from `pdMat`, and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the `pdMat` class of `object`.

**Usage**

```
pdMat(value, form, nam, data, pdClass)
```

**Arguments**

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code>   | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.                                                                      |
| <code>form</code>    | an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .                          |
| <code>nam</code>     | an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .                                                  |
| <code>data</code>    | an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| <code>pdClass</code> | an optional character string naming the <code>pdMat</code> class to be assigned to the returned object. This argument will only be used when <code>value</code> is not a <code>pdMat</code> object. Defaults to " <code>pdSymm</code> ".                                                                                                                                                                         |

**Value**

a `pdMat` object representing a positive-definite matrix, inheriting from the class named in `pdClass`, or from `class(object)`, if `object` inherits from `pdMat`.

|--------------------------------|-----------------------------------------------------------------------------------|
| <code>pdMatrix.reStruct</code> | <i>Extract Matrix or Square-Root Factor from Components of an reStruct Object</i> |
|--------------------------------|-----------------------------------------------------------------------------------|

---

**Description**

This method function extracts the positive-definite matrices corresponding to the pdMat elements of object, or square-root factors of the positive-definite matrices.

**Usage**

```
S3 method for class 'reStruct'
pdMatrix(object, factor)
```

**Arguments**

- `object` an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of `pdMat` objects.  
`factor` an optional logical value. If TRUE, square-root factors of the positive-definite matrices represented by the elements of `object` are returned; else, if FALSE, the positive-definite matrices are returned. Defaults to FALSE.

**Value**

a list with components given by the positive-definite matrices corresponding to the elements of object, or square-root factors of the positive-definite matrices.

pdNatural

*General Positive-Definite Matrix in Natural Parametrization*

## Description

This function is a constructor for the *pdNatural* class, representing a general positive-definite matrix, using a natural parametrization . If the matrix associated with object is of dimension  $n$ , it is represented by  $n(n + 1)/2$  parameters. Letting  $\sigma_{ij}$  denote the  $ij$ -th element of the underlying positive definite matrix and  $\rho_{ij} = \sigma_i / \sqrt{\sigma_{ii}\sigma_{jj}}$ ,  $i \neq j$  denote the associated "correlations", the "natural" parameters are given by  $\sqrt{\sigma_{ii}}$ ,  $i = 1, \dots, n$  and  $\log((1 + \rho_{ij})/(1 - \rho_{ij}))$ ,  $i \neq j$ . Note that all natural parameters are individually unrestricted, but not jointly unrestricted (meaning that not all unrestricted vectors would give positive-definite matrices). Therefore, this parametrization should NOT be used for optimization. It is mostly used for deriving approximate confidence intervals on parameters following the optimization of an objective function. When *value* is *numeric(0)*, an uninitialized *pdMat* object, a one-sided formula, or a vector of character strings, *object* is returned as an uninitialized *pdSymm* object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the *coef* or *matrix* replacement functions. If *value* is an initialized *pdMat* object, *object* will be constructed from *as.matrix(value)*. Finally, if *value* is a numeric vector, it is assumed to represent the natural parameters of the underlying positive-definite matrix.

## Usage

```
pdNatural(value, form, nam, data)
```

## Arguments

|              |                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>value</i> | an optional initialization value, which can be any of the following: a <i>pdMat</i> object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to <i>numeric(0)</i> , corresponding to an uninitialized object.                                                                      |
| <i>form</i>  | an optional one-sided linear formula specifying the row/column names for the matrix represented by <i>object</i> . Because factors may be present in <i>form</i> , the formula needs to be evaluated on a <i>data.frame</i> to resolve the names it defines. This argument is ignored when <i>value</i> is a one-sided formula. Defaults to NULL.                                      |
| <i>nam</i>   | an optional vector of character strings specifying the row/column names for the matrix represented by <i>object</i> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <i>value</i> is a vector of character strings. Defaults to NULL.                                                  |
| <i>data</i>  | an optional data frame in which to evaluate the variables named in <i>value</i> and <i>form</i> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |

## Value

a *pdNatural* object representing a general positive-definite matrix in natural parametrization, also inheriting from class *pdMat*.

pdSymm

*General Positive-Definite Matrix*

---

**Description**

This function is a constructor for the `pdSymm` class, representing a general positive-definite matrix. If the matrix associated with object is of dimension  $n$ , it is represented by  $n(n + 1)/2$  unrestricted parameters, using the matrix-logarithm parametrization described in Pinheiro and Bates (1996). When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

**Usage**

```
pdSymm(value, form, nam, data)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code> | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.                                             |
| <code>form</code>  | an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> . |
| <code>nam</code>   | an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .                         |

**data** an optional data frame in which to evaluate the variables named in **value** and **form**. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying matrix. If **NULL**, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.

### Value

a **pdSymm** object representing a general positive-definite matrix, also inheriting from class **pdMat**.

pd1
```

### Description

The Phenobarb data frame has 744 rows and 7 columns.

### Format

This data frame contains the following columns:

**Subject** an ordered factor identifying the infant.

**Wt** a numeric vector giving the birth weight of the infant (kg).

**Apgar** an ordered factor giving the 5-minute Apgar score for the infant. This is an indication of health of the newborn infant.

**ApgarInd** a factor indicating whether the 5-minute Apgar score is < 5 or >= 5.

**time** a numeric vector giving the time when the sample is drawn or drug administered (hr).

**dose** a numeric vector giving the dose of drug administered (ug/kg).

**conc** a numeric vector giving the phenobarbital concentration in the serum (ug/L).

## Details

Data from a pharmacokinetics study of phenobarbital in neonatal infants. During the first few days of life the infants receive multiple doses of phenobarbital for prevention of seizures. At irregular intervals blood samples are drawn and serum phenobarbital concentrations are determined. The data were originally given in Grasela and Donn(1985) and are analyzed in Boeckmann, Sheiner and Beal (1994), in Davidian and Giltinan (1995), and in Littell et al. (1996).

phenoModel

*Model function for the Phenobarb data*

---

## Description

A model function for a model used with the Phenobarb data. This function uses compiled C code to improve execution speed.

## Usage

```
phenoModel(Subject, time, dose, lC1, lV)
```

## Arguments

|         |                                                                                                                       |
|---------|-----------------------------------------------------------------------------------------------------------------------|
| Subject | an integer vector of subject identifiers. These should be sorted in increasing order.                                 |
| time    | numeric. A vector of the times at which the sample was drawn or the drug administered (hr).                           |
| dose    | numeric. A vector of doses of drug administered (ug/kg).                                                              |
| lC1     | numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.              |
| lV      | numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time. |

## Details

See the details section of [Phenobarb](#) for a description of the model function that phenoModel evaluates.

2900

*Pixel*

### Value

a numeric vector of predicted phenobarbital concentrations.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Pixel

*X-ray pixel intensities over time*

---

### Description

The Pixel data frame has 102 rows and 4 columns of data on the pixel intensities of CT scans of dogs over time

### Format

This data frame contains the following columns:

**Dog** a factor with levels 1 to 10 designating the dog on which the scan was made

**Side** a factor with levels L and R designating the side of the dog being scanned

**day** a numeric vector giving the day post injection of the contrast on which the scan was made

**pixel** a numeric vector of pixel intensities

### Source

Pinheiro, J. C. and Bates, D. M. (2000) *Mixed-effects Models in S and S-PLUS*, Springer.

### Examples

```
fm1 <- lme(pixel ~ day + I(day^2), data = Pixel,
 random = list(Dog = ~ day, Side = ~ 1))
summary(fm1)
VarCorr(fm1)
```

---

**plot.ACF***Plot an ACF Object*

---

**Description**

an xyplot of the autocorrelations versus the lags, with type = "h", is produced. If alpha > 0, curves representing the critical limits for a two-sided test of level alpha for the autocorrelations are added to the plot.

**Usage**

```
S3 method for class 'ACF'
plot(x, alpha, xlab, ylab, grid, ...)
```

**Arguments**

- x an object inheriting from class ACF, consisting of a data frame with two columns named lag and ACF, representing the autocorrelation values and the corresponding lags.
- alpha an optional numeric value with the significance level for testing if the autocorrelations are zero. Lines corresponding to the lower and upper critical values for a test of level alpha are added to the plot. Default is 0, in which case no lines are plotted.
- xlab, ylab optional character strings with the x- and y-axis labels. Default respectively to "Lag" and "Autocorrelation".
- grid an optional logical value indicating whether a grid should be added to plot. Default is FALSE.
- ... optional arguments passed to the xyplot function.

**Value**

an xyplot Trellis plot.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[ACF](#), [xyplot](#)

**Examples**

```
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
plot(ACF(fm1, maxLag = 10), alpha = 0.01)
```

**plot.augPred***Plot an augPred Object***Description**

A Trellis xyplot of predictions versus the primary covariate is generated, with a different panel for each value of the grouping factor. Predicted values are joined by lines, with different line types (colors) being used for each level of grouping. Original observations are represented by circles.

**Usage**

```
S3 method for class 'augPred'
plot(x, key, grid, ...)
```

**Arguments**

- |                   |                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>    | an object of class <code>augPred</code> .                                                                                                                                                                                                                                                                                                                                  |
| <code>key</code>  | an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, <code>key</code> is passed down as an argument to the <code>trellis</code> function generating the plots ( <code>xyplot</code> ). Defaults to TRUE. |
| <code>grid</code> | an optional logical value indicating whether a grid should be added to plot. Default is FALSE.                                                                                                                                                                                                                                                                             |
| <code>...</code>  | optional arguments passed down to the <code>trellis</code> function generating the plots.                                                                                                                                                                                                                                                                                  |

**Value**

A Trellis plot of predictions versus the primary covariate, with panels determined by the grouping factor.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**plot.compareFits**      *Plot a compareFits Object*

---

**Description**

A Trellis dotplot of the values being compared, with different rows per group, is generated, with a different panel for each coefficient. Different symbols (colors) are used for each object being compared.

**Usage**

```
S3 method for class 'compareFits'
plot(x, subset, key, mark, ...)
```

**Arguments**

|        |                                                                                                                                                                                                                                                                                                                                                      |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x      | an object of class <code>compareFits</code> .                                                                                                                                                                                                                                                                                                        |
| subset | an optional logical or integer vector specifying which rows of x should be used in the plots. If missing, all rows are used.                                                                                                                                                                                                                         |
| key    | an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the <code>trellis</code> function generating the plots (dotplot). Defaults to TRUE. |
| mark   | an optional numeric vector, of length equal to the number of coefficients being compared, indicating where vertical lines should be drawn in the plots. If missing, no lines are drawn.                                                                                                                                                              |
| ...    | optional arguments passed down to the <code>trellis</code> function generating the plots.                                                                                                                                                                                                                                                            |

**Value**

A Trellis dotplot of the values being compared, with rows determined by the groups and panels by the coefficients.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Not run:
fm1 <- lmList(Orthodont)
fm2 <- lme(Orthodont)
plot(compareFits(coef(fm1), coef(fm2)))

End(Not run)
```

---

**plot.gls***Plot a gls Object*

---

**Description**

Diagnostic plots for the linear model fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

**Usage**

```
S3 method for class 'gls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```

**Arguments**

- |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>form</code>      | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "p") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting. |
| <code>abline</code>    | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.                                                                                                                                                                                                                                                                             |
| <code>id</code>        | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.               |
| <code>idLabels</code>  | an optional vector, or one-sided formula. If given as a vector, it is converted to character mode and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character mode and used to label the identified observations. Default is the innermost grouping factor.                                                                                                                                                                                              |
| <code>idResType</code> | an optional character string specifying the type of residuals to be used in identifying outliers, when <code>id</code> is a numeric value. If "pearson", the standardized                                                                                                                                                                                                                                                                                                                                                                                                                |

residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

- grid** an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if `xyplot` defaults to TRUE, else defaults to FALSE.
- ...** optional arguments passed to the Trellis plot function.

### Value

a diagnostic Trellis plot.

### Examples

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
 correlation = corAR1(form = ~ 1 | Mare))
standardized residuals versus fitted values by Mare
plot(fm1, resid(., type = "p") ~ fitted(.) | Mare, abline = 0)
box-plots of residuals by Mare
plot(fm1, Mare ~ resid(.))
observed versus fitted values by Mare
plot(fm1, follicles ~ fitted(.) | Mare, abline = c(0,1))
```

**plot.intervals.lmList** *Plot lmList Confidence Intervals*

### Description

A Trellis dot-plot of the confidence intervals on the linear model coefficients is generated, with a different panel for each coefficient. Rows in the dot-plot correspond to the names of the `lm` components of the `lmList` object used to produce `x`. The lower and upper confidence limits are connected by a line segment and the estimated coefficients are marked with a "+". The Trellis function `dotplot` is used in this method function.

### Usage

```
S3 method for class 'intervals.lmList'
plot(x, ...)
```

**Arguments**

- x an object inheriting from class `intervals.lmList`, representing confidence intervals and estimates for the coefficients in the `lm` components of the `lmList` object used to produce x.
- ... optional arguments passed to the Trellis `dotplot` function.

**Value**

a Trellis plot with the confidence intervals on the coefficients of the individual `lm` components of the `lmList` that generated x.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`intervals.lmList`, `lmList`, `dotplot`

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
plot(intervals(fm1))
```

**plot.lme**

*Plot an lme or nls object*

**Description**

Diagnostic plots for the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

**Usage**

```
S3 method for class 'lme'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
S3 method for class 'nls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```

### Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model, or from <code>nls</code> , representing an fitted nonlinear least squares model.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>form</code>      | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "p") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.                      |
| <code>abline</code>    | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.                                                                                                                                                                                                                                                                                                  |
| <code>id</code>        | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized, or normalized residuals. Observations with absolute standardized (normalized) residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified. |
| <code>idLabels</code>  | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.                                                                                                                                                                                                                             |
| <code>idResType</code> | an optional character string specifying the type of residuals to be used in identifying outliers, when <code>id</code> is a numeric value. If "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals premultiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".                                                       |
| <code>grid</code>      | an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xyplot</code> defaults to TRUE, else defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                               |
| ...                    | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### Value

a diagnostic Trellis plot.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lme`, `xyplot`, `bwplot`, `histogram`

## Examples

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
standardized residuals versus fitted values by gender
plot(fm1, resid(., type = "p") ~ fitted(.) | Sex, abline = 0)
box-plots of residuals by Subject
plot(fm1, Subject ~ resid(.))
observed versus fitted values by Subject
plot(fm1, distance ~ fitted(.) | Subject, abline = c(0,1))
```

**plot.lmList**

*Plot an lmList Object*

## Description

Diagnostic plots for the linear model fits corresponding to the *x* components are obtained. The *form* argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a *|* operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If *form* is a one-sided formula, histograms of the variable on the right hand side of the formula, before a *|* operator, are displayed (the Trellis function *histogram* is used). If *form* is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function *xyplot* is used). Finally, if *form* is two-sided and its left had side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function *bwplot* is used).

## Usage

```
S3 method for class 'lmList'
plot(x, form, abline, id, idLabels, grid, ...)
```

## Arguments

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>x</i>      | an object inheriting from class <i>lmList</i> , representing a list of <i>lm</i> objects with a common model.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>form</i>   | an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <i>x</i> can be referenced. In addition, <i>x</i> itself can be referenced in the formula using the symbol <i>"."</i> . Conditional expressions on the right of a <i> </i> operator can be used to define separate panels in a Trellis display. Default is <i>resid(., type = "pool") ~ fitted(.)</i> , corresponding to a plot of the standardized residuals (using a pooled estimate for the residual standard error) versus fitted values.       |
| <i>abline</i> | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.                                                                                                                                                                                                                                                                |
| <i>id</i>     | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <i>idLabels</i> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified. |

- idLabels** an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to **id**. If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is `getGroups(x)`.
- grid** an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if `xyplot` defaults to TRUE, else defaults to FALSE.
- ...** optional arguments passed to the Trellis plot function.

### Value

a diagnostic Trellis plot.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lmList`, `predict.lm`, `xyplot`, `bwplot`, `histogram`

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
standardized residuals versus fitted values by gender
plot(fm1, resid(., type = "pool") ~ fitted(.) | Sex, abline = 0, id = 0.05)
box-plots of residuals by Subject
plot(fm1, Subject ~ resid(.))
observed versus fitted values by Subject
plot(fm1, distance ~ fitted(.) | Subject, abline = c(0,1))
```

**plot.nffGroupedData** *Plot an nffGroupedData Object*

### Description

A Trellis dot-plot of the response by group is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. The Trellis function `dotplot` is used.

### Usage

```
S3 method for class 'nffGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, panel, key,
 grid, ...)
```

**Arguments**

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>           | an object inheriting from class <code>nffGroupedData</code> , representing a <code>groupedData</code> object with a factor primary covariate and a single grouping level.                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>outer</code>       | an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to TRUE, <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used. |
| <code>inner</code>       | an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to TRUE, <code>attr(object, "inner")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.                                                                                                                        |
| <code>innerGroups</code> | an optional one-sided formula specifying a factor to be used for grouping the levels of the inner covariate. Different colors, or symbols, are used for each level of the <code>innerGroups</code> factor. Default is NULL, meaning that no <code>innerGroups</code> covariate is present.                                                                                                                                                                                                                                                                     |
| <code>xlab</code>        | an optional character string with the label for the horizontal axis. Default is the <code>y</code> elements of <code>attr(object, "labels")</code> and <code>attr(object, "units")</code> pasted together.                                                                                                                                                                                                                                                                                                                                                     |
| <code>ylab</code>        | an optional character string with the label for the vertical axis. Default is the grouping factor name.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>strip</code>       | an optional function passed as the <code>strip</code> argument to the <code>dotplot</code> function. Default is <code>strip.default(..., style = 1)</code> (see <code>trellis.args</code> ).                                                                                                                                                                                                                                                                                                                                                                   |
| <code>panel</code>       | an optional function used to generate the individual panels in the Trellis display, passed as the <code>panel</code> argument to the <code>dotplot</code> function.                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>key</code>         | an optional logical function or function. If TRUE and either <code>inner</code> or <code>innerGroups</code> are non-NULL, a legend for the different inner ( <code>innerGroups</code> ) levels is included at the top of the plot. If given as a function, it is passed as the <code>key</code> argument to the <code>dotplot</code> function. Default is TRUE if either <code>inner</code> or <code>innerGroups</code> are non-NULL and FALSE otherwise.                                                                                                      |
| <code>grid</code>        | this argument is included for consistency with the <code>plot.nfnGroupedData</code> method calling sequence. It is ignored in this method function.                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>...</code>         | optional arguments passed to the <code>dotplot</code> function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Value**

a Trellis dot-plot of the response by group.

**Examples**

```
plot(Machines)
plot(Machines, inner = TRUE)
```

**plot.nfnGroupedData**     *Plot an nfnGroupedData Object*

**Description**

A Trellis plot of the response versus the primary covariate is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. Otherwise, the levels of the grouping variable determine the panels. A scatter plot of the response versus the primary covariate is displayed in each panel, with observations corresponding to same inner group joined by line segments. The Trellis function `xyplot` is used.

**Usage**

```
S3 method for class 'nfnGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, aspect, panel,
 key, grid, ...)
```

**Arguments**

- x** an object inheriting from class `nfnGroupedData`, representing a `groupedData` object with a numeric primary covariate and a single grouping level.
- outer** an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to `TRUE`, `attr(object, "outer")` is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to `NULL`, meaning that no outer covariates are to be used.
- inner** an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to `TRUE`, `attr(object, "inner")` is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to `NULL`, meaning that no inner covariate is present.
- innerGroups** an optional one-sided formula specifying a factor to be used for grouping the levels of the inner covariate. Different colors, or line types, are used for each level of the `innerGroups` factor. Default is `NULL`, meaning that no `innerGroups` covariate is present.
- xlab, ylab** optional character strings with the labels for the plot. Default is the corresponding elements of `attr(object, "labels")` and `attr(object, "units")` pasted together.

|                     |                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>strip</code>  | an optional function passed as the <code>strip</code> argument to the <code>xyplot</code> function. Default is <code>strip.default(..., style = 1)</code> (see <code>trellis.args</code> ).                                                                                                                                                                                        |
| <code>aspect</code> | an optional character string indicating the aspect ratio for the plot passed as the <code>aspect</code> argument to the <code>xyplot</code> function. Default is "xy" (see <code>trellis.args</code> ).                                                                                                                                                                            |
| <code>panel</code>  | an optional function used to generate the individual panels in the Trellis display, passed as the <code>panel</code> argument to the <code>xyplot</code> function.                                                                                                                                                                                                                 |
| <code>key</code>    | an optional logical function or function. If TRUE and <code>innerGroups</code> is non-NULL, a legend for the different <code>innerGroups</code> levels is included at the top of the plot. If given as a function, it is passed as the <code>key</code> argument to the <code>xyplot</code> function. Default is TRUE if <code>innerGroups</code> is non-NULL and FALSE otherwise. |
| <code>grid</code>   | an optional logical value indicating whether a grid should be added to plot. Default is TRUE.                                                                                                                                                                                                                                                                                      |
| ...                 | optional arguments passed to the <code>xyplot</code> function.                                                                                                                                                                                                                                                                                                                     |

**Value**

a Trellis plot of the response versus the primary covariate.

**Examples**

```
different panels per Subject
plot(Orthodont)
different panels per gender
plot(Orthodont, outer = TRUE)
```

**plot.nmGroupedData**      *Plot an nmGroupedData Object*

**Description**

The `groupedData` object is summarized by the values of the `displayLevel` grouping factor (or the combination of its values and the values of the covariate indicated in `preserve`, if any is present). The collapsed data is used to produce a new `groupedData` object, with grouping factor given by the `displayLevel` factor, which is plotted using the appropriate plot method for `groupedData` objects with single level of grouping.

**Usage**

```
S3 method for class 'nmGroupedData'
plot(x, collapseLevel, displayLevel, outer, inner,
 preserve, FUN, subset, key, grid, ...)
```

**Arguments**

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>             | an object inheriting from class <code>nmGroupedData</code> , representing a <code>groupedData</code> object with multiple grouping factors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>collapseLevel</b> | an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>displayLevel</b>  | an optional positive integer or character string indicating the grouping level to use for determining the panels in the Trellis display, when <code>outer</code> is missing. Default is <code>collapseLevel</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>outer</b>         | an optional logical value or one-sided formula, indicating covariates that are outer to the <code>displayLevel</code> grouping factor, which are used to determine the panels of the Trellis plot. If equal to TRUE, the <code>displayLevel</code> element <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>inner</b>         | an optional logical value or one-sided formula, indicating a covariate that is inner to the <code>displayLevel</code> grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to TRUE, <code>attr(object, "outer")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to NULL, meaning that no inner covariate is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>preserve</b>      | an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the <code>collapseLevel</code> grouping factor. The collapsing factor is obtained by pasting together the levels of the <code>collapseLevel</code> grouping factor and the values of the covariate to be preserved. Default is NULL, meaning that no covariates need to be preserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>FUN</b>           | an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in <code>object</code> that vary within the groups defined by <code>collapseLevel</code> . Invariant variables are always summarized by group using the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the data such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable. |
| <b>subset</b>        | an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be used for plotting the data. Default is NULL, meaning that all levels are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|      |                                                                                                                                                                                                                                                                                                                                                               |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| key  | an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the <code>trellis</code> function generating the plots ( <code>xyplot</code> ). Defaults to TRUE. |
| grid | an optional logical value indicating whether a grid should be added to plot. Default is TRUE.                                                                                                                                                                                                                                                                 |
| ...  | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                       |

**Value**

a Trellis display of the data collapsed over the values of the `collapseLevel` grouping factor and grouped according to the `displayLevel` grouping factor.

**Examples**

```
no collapsing, panels by Dog
plot(Pixel, display = "Dog", inner = ~Side)
collapsing by Dog, preserving day
plot(Pixel, collapse = "Dog", preserve = ~day)
```

**plot.ranef.lme**

*Plot a ranef.lme Object*

**Description**

If `form` is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the `form` argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in `form`, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if `form` specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function `dotplot` is used in this method function.

If `form` is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of `form`. Scatter plots are generated for numeric variables and boxplots are generated for categorical (factor or ordered) variables.

### Usage

```
S3 method for class 'ranef.lme'
plot(x, form, omitFixed, level, grid, control, ...)
```

### Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | an object inheriting from class <code>ranef.lme</code> , representing the estimated coefficients or estimated random effects for the <code>lme</code> object from which it was produced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| form      | an optional formula specifying the desired type of plot. If given as a one-sided formula, a dotplot of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in <code>form</code> is returned. Single factors ( <code>~g</code> ) or crossed factors ( <code>~g1*g2</code> ) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in <code>x</code> separated by <code>+</code> . A Trellis display of the random effect (coefficient) versus the named covariates is returned in this case. Default is <code>NULL</code> , in which case the row names of the random effects (coefficients) are used.                                                                                                                                                                                                                                                                                                                          |
| omitFixed | an optional logical value indicating whether columns with values that are constant across groups should be omitted. Default is <code>TRUE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| level     | an optional integer value giving the level of grouping to be used for <code>x</code> . Only used when <code>x</code> is a list with different components for each grouping level. Defaults to the highest or innermost level of grouping.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| grid      | an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in <code>form</code> . Default is <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| control   | an optional list with control values for the plot, when <code>form</code> is given as a two-sided formula. The control values are referenced by name in the <code>control</code> list and only the ones to be modified from the default need to be specified. Available values include: <code>drawLine</code> , a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is <code>TRUE</code> ); <code>span.loess</code> , used as the <code>span</code> argument in the call to <code>panel.loess</code> (default is <code>2/3</code> ); <code>degree.loess</code> , used as the <code>degree</code> argument in the call to <code>panel.loess</code> (default is <code>1</code> ); <code>cex.axis</code> , the character expansion factor for the x-axis (default is <code>0.8</code> ); <code>srt.axis</code> , the rotation factor for the x-axis (default is <code>0</code> ); and <code>mgp.axis</code> , the margin parameters for the x-axis (default is <code>c(2, 0.5, 0)</code> ). |
| ...       | optional arguments passed to the Trellis dotplot function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### Value

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
Not run:
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
plot(ranef(fm1))
fm1RE <- ranef(fm1, aug = TRUE)
plot(fm1RE, form = ~ Sex)
plot(fm1RE, form = age ~ Sex)

End(Not run)
```

**plot.ranef.lmList**      *Plot a ranef.lmList Object*

## Description

If `form` is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the `form` argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in `form`, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if `form` specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function `dotplot` is used in this method function.

If `form` is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of `form`. Scatter plots are generated for numeric variables and boxplots are generated for categorical (`factor` or `ordered`) variables.

## Usage

```
S3 method for class 'ranef.lmList'
plot(x, form, grid, control, ...)
```

## Arguments

- `x` an object inheriting from class `ranef.lmList`, representing the estimated coefficients or estimated random effects for the `lmList` object from which it was produced.
- `form` an optional formula specifying the desired type of plot. If given as a one-sided formula, a dotplot of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in `form` is returned. Single factors (`~g`) or crossed factors (`~g1*g2`) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in `x` separated by `+`. A Trellis display of the random effect (coefficient) versus the named covariates is returned in this case. Default is `NULL`, in which case the row names of the random effects (coefficients) are used.
- `grid` an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in `form`. Default is `FALSE`.
- `control` an optional list with control values for the plot, when `form` is given as a two-sided formula. The control values are referenced by name in the `control` list and only the ones to be modified from the default need to be specified. Available

values include: `drawLine`, a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is TRUE); `span.loess`, used as the `span` argument in the call to `panel.loess` (default is 2/3); `degree.loess`, used as the `degree` argument in the call to `panel.loess` (default is 1); `cex.axis`, the character expansion factor for the x-axis (default is 0.8); `srt.axis`, the rotation factor for the x-axis (default is 0); and `mgp.axis`, the margin parameters for the x-axis (default is `c(2, 0.5, 0)`).

... optional arguments passed to the Trellis `dotplot` function.

### Value

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`lmList`, `dotplot`

### Examples

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
plot(ranef(fm1))
fm1RE <- ranef(fm1, aug = TRUE)
plot(fm1RE, form = ~ Sex)
Not run: plot(fm1RE, form = age ~ Sex)
```

`plot.Variogram`

*Plot a Variogram Object*

### Description

an xyplot of the semi-variogram versus the distances is produced. If `smooth` = TRUE, a loess smoother is added to the plot. If `showModel` = TRUE and `x` includes an "modelVario" attribute, the corresponding semi-variogram is added to the plot.

### Usage

```
S3 method for class 'Variogram'
plot(x, smooth, showModel, sigma, span, xlab,
 ylab, type, ylim, grid, ...)
```

### Arguments

- |                     |                                                                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>      | an object inheriting from class <code>Variogram</code> , consisting of a data frame with two columns named <code>vario</code> and <code>dist</code> , representing the semi-variogram values and the corresponding distances. |
| <code>smooth</code> | an optional logical value controlling whether a loess smoother should be added to the plot. Defaults to TRUE, when <code>showModel</code> is FALSE.                                                                           |

|                         |                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>showModel</code>  | an optional logical value controlling whether the semi-variogram corresponding to an "modelVariog" attribute of <code>x</code> , if any is present, should be added to the plot. Defaults to TRUE, when the "modelVariog" attribute is present. |
| <code>sigma</code>      | an optional numeric value used as the height of a horizontal line displayed in the plot. Can be used to represent the process standard deviation. Default is NULL, implying that no horizontal line is drawn.                                   |
| <code>span</code>       | an optional numeric value with the smoothing parameter for the loess fit. Default is 0.6.                                                                                                                                                       |
| <code>xlab, ylab</code> | optional character strings with the x- and y-axis labels. Default respectively to "Distance" and "SemiVariogram".                                                                                                                               |
| <code>type</code>       | an optional character indicating the type of plot. Defaults to "p".                                                                                                                                                                             |
| <code>ylim</code>       | an optional numeric vector with the limits for the y-axis. Defaults to <code>c(0, max(x\$variog))</code> .                                                                                                                                      |
| <code>grid</code>       | an optional logical value indicating whether a grid should be added to plot. Default is FALSE.                                                                                                                                                  |
| <code>...</code>        | optional arguments passed to the Trellis <code>xyplot</code> function.                                                                                                                                                                          |

**Value**

an `xyplot` Trellis plot.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[Variogram](#), [xyplot](#), [loess](#)

**Examples**

```
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
plot(Variogram(fm1, form = ~ Time | Mare, maxDist = 0.7))
```

**pooledSD**

*Extract Pooled Standard Deviation*

**Description**

The pooled estimated standard deviation is obtained by adding together the residual sum of squares for each non-null element of `object`, dividing by the sum of the corresponding residual degrees-of-freedom, and taking the square-root.

**Usage**

```
pooledSD(object)
```

**Arguments**

|                     |                                                       |
|---------------------|-------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>lmList</code> . |
|---------------------|-------------------------------------------------------|

**Value**

the pooled standard deviation for the non-null elements of object, with an attribute df with the number of degrees-of-freedom used in the estimation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

predict.gls

*Predictions from a gls Object*

---

**Description**

The predictions for the linear model represented by object are obtained at the covariate values defined in newdata.

**Usage**

```
S3 method for class 'gls'
predict(object, newdata, na.action, ...)
```

**Arguments**

|           |                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model.                                                                                                          |
| newdata   | an optional data frame to be used for obtaining the predictions. All variables used in the linear model must be present in the data frame. If missing, the fitted values are returned.                                    |
| na.action | a function that indicates what should happen when newdata contains NAs. The default action ( <code>na.fail</code> ) causes the function to print an error message and terminate if there are any incomplete observations. |
| ...       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                 |

**Value**

a vector with the predicted values.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**[gls](#)**Examples**

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
 correlation = corAR1(form = ~ 1 | Mare))
newOvary <- data.frame(Time = c(-0.75, -0.5, 0, 0.5, 0.75))
predict(fm1, newOvary)
```

predict.gnls

*Predictions from a gnls Object***Description**

The predictions for the nonlinear model represented by `object` are obtained at the covariate values defined in `newdata`.

**Usage**

```
S3 method for class 'gnls'
predict(object, newdata, na.action, naPattern, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                        |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | an object inheriting from class <code>gnls</code> , representing a generalized nonlinear least squares fitted model.                                                                                                                   |
| <code>newdata</code>   | an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model must be present in the data frame. If missing, the fitted values are returned.                                              |
| <code>na.action</code> | a function that indicates what should happen when <code>newdata</code> contains NAs. The default action ( <code>na.fail</code> ) causes the function to print an error message and terminate if there are any incomplete observations. |
| <code>naPattern</code> | an expression or formula object, specifying which returned values are to be regarded as missing.                                                                                                                                       |
| <code>...</code>       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                              |

**Value**

a vector with the predicted values.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**[gnls](#)

## Examples

```
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
 weights = varPower())
newSoybean <- data.frame(Time = c(10,30,50,80,100))
predict(fm1, newSoybean)
```

### `predict.lme`

*Predictions from an lme Object*

## Description

The predictions at level  $i$  are obtained by adding together the population predictions (based only on the fixed effects estimates) and the estimated contributions of the random effects to the predictions at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ . If group values not included in the original grouping factors are present in `newdata`, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

## Usage

```
S3 method for class 'lme'
predict(object, newdata, level, asList, na.action, ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                 |
| <code>newdata</code>   | an optional data frame to be used for obtaining the predictions. All variables used in the fixed and random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.                                          |
| <code>level</code>     | an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping. |
| <code>asList</code>    | an optional logical value. If TRUE and a single value is given in <code>level</code> , the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> .               |
| <code>na.action</code> | a function that indicates what should happen when <code>newdata</code> contains NAs. The default action ( <code>na.fail</code> ) causes the function to print an error message and terminate if there are any incomplete observations.                                               |
| <code>...</code>       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                            |

## Value

if a single level of grouping is specified in `level`, the returned value is either a list with the predictions split by groups (`asList` = TRUE) or a vector with the predictions (`asList` = FALSE); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lme](#), [fitted.lme](#)

**Examples**

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
newOrth <- data.frame(Sex = c("Male", "Male", "Female", "Female", "Male", "Male"),
 age = c(15, 20, 10, 12, 2, 4),
 Subject = c("M01", "M01", "F30", "F30", "M04", "M04"))
predict(fm1, newOrth, level = 0:1)
```

*predict.lmList*

*Predictions from an lmList Object*

**Description**

If the grouping factor corresponding to object is included in newdata, the data frame is partitioned according to the grouping factor levels; else, newdata is repeated for all *lm* components. The predictions and, optionally, the standard errors for the predictions, are obtained for each *lm* component of object, using the corresponding element of the partitioned newdata, and arranged into a list with as many components as object, or combined into a single vector or data frame (if se.fit=TRUE).

**Usage**

```
S3 method for class 'lmList'
predict(object, newdata, subset, pool, asList, se.fit, ...)
```

**Arguments**

|                |                                                                                                                                                                                                                    |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>object</i>  | an object inheriting from class <i>lmList</i> , representing a list of <i>lm</i> objects with a common model.                                                                                                      |
| <i>newdata</i> | an optional data frame to be used for obtaining the predictions. All variables used in the object model formula must be present in the data frame. If missing, the same data frame used to produce object is used. |
| <i>subset</i>  | an optional character or integer vector naming the <i>lm</i> components of object from which the predictions are to be extracted. Default is NULL, in which case all components are used.                          |
| <i>asList</i>  | an optional logical value. If TRUE, the returned object is a list with the predictions split by groups; else the returned value is a vector. Defaults to FALSE.                                                    |
| <i>pool</i>    | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object, "pool").                                                                     |
| <i>se.fit</i>  | an optional logical value indicating whether pointwise standard errors should be computed along with the predictions. Default is FALSE.                                                                            |
| ...            | some methods for this generic require additional arguments. None are used in this method.                                                                                                                          |

**Value**

a list with components given by the predictions (and, optionally, the standard errors for the predictions) from each lm component of object, a vector with the predictions from all lm components of object, or a data frame with columns given by the predictions and their corresponding standard errors.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lmList](#), [predict.lm](#)

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
predict(fm1, se.fit = TRUE)
```

---

predict.nlme

*Predictions from an nlme Object*

---

**Description**

The predictions at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters. If group values not included in the original grouping factors are present in newdata, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

**Usage**

```
S3 method for class 'nlme'
predict(object, newdata, level, asList, na.action,
naPattern, ...)
```

**Arguments**

|         |                                                                                                                                                                                                                                                                                      |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | an object inheriting from class <code>nlme</code> , representing a fitted nonlinear mixed-effects model.                                                                                                                                                                             |
| newdata | an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model, the fixed and the random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.                 |
| level   | an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping. |
| asList  | an optional logical value. If TRUE and a single value is given in level, the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of level.                                           |

|                        |                                                                                                                                                                                                                                        |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>na.action</code> | a function that indicates what should happen when <code>newdata</code> contains NAs. The default action ( <code>na.fail</code> ) causes the function to print an error message and terminate if there are any incomplete observations. |
| <code>naPattern</code> | an expression or formula object, specifying which returned values are to be regarded as missing.                                                                                                                                       |
| <code>...</code>       | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                              |

### Value

if a single level of grouping is specified in `level`, the returned value is either a list with the predictions split by groups (`asList = TRUE`) or a vector with the predictions (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

### Examples

```
fm1 <- nlme(height ~ SSasymp(age, Asym, R0, lrc),
 data = Loblolly,
 fixed = Asym + R0 + lrc ~ 1,
 random = Asym ~ 1,
 start = c(Asym = 103, R0 = -8.5, lrc = -3.3))
newLoblolly <- data.frame(age = c(5,10,15,20,25,30),
 Seed = rep(301,6))
predict(fm1, newLoblolly, level = 0:1)
```

**print.summary.pdMat** *Print a summary.pdMat Object*

### Description

The standard deviations and correlations associated with the positive-definite matrix represented by `object` (considered as a variance-covariance matrix) are printed, together with the formula and the grouping level associated `object`, if any are present.

### Usage

```
S3 method for class 'summary.pdMat'
print(x, sigma, rdig, Level, resid, ...)
```

**Arguments**

- x an object inheriting from class `summary.pdMat`, generally resulting from applying `summary` to an object inheriting from class `pdMat`.
- `sigma` an optional numeric value used as a multiplier for the square-root factor of the positive-definite matrix represented by `object` (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.
- `rdig` an optional integer value with the number of significant digits to be used in printing correlations. Defaults to 3.
- `Level` an optional character string with a description of the grouping level associated with `object` (generally corresponding to levels of grouping in a mixed-effects model). Defaults to `NULL`.
- `resid` an optional logical value. If `TRUE` an extra row with the "residual" standard deviation given in `sigma` will be included in the output. Defaults to `FALSE`.
- ... optional arguments passed to `print.default`; see the documentation on that method function.

**Examples**

```
pd1 <- pdCompSymm(3 * diag(2) + 1, form = ~age + age^2,
 data = Orthodont)
print(summary(pd1), sigma = 1.2, resid = TRUE)
```

`print.varFunc`

*Print a varFunc Object*

**Description**

The class and the coefficients associated with `x` are printed.

**Usage**

```
S3 method for class 'varFunc'
print(x, ...)
```

**Arguments**

- x an object inheriting from class `varFunc`, representing a variance function structure.
- ... optional arguments passed to `print.default`; see the documentation on that method function.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
vf1 <- varPower(0.3, form = ~age)
vf1 <- Initialize(vf1, Orthodont)
print(vf1)
```

*qqnorm.gls*

*Normal Plot of Residuals from a gls Object*

**Description**

Diagnostic plots for assessing the normality of residuals the generalized least squares fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

**Usage**

```
S3 method for class 'gls'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>      | an object inheriting from class <code>gls</code> , representing a generalized least squares fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>form</code>   | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>y</code> can be referenced. In addition, <code>y</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> and to the left of a <code> </code> operator must evaluate to a residuals vector. Default is <code>~ resid(., type = "p")</code> , corresponding to a normal plot of the standardized residuals. |
| <code>abline</code> | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.                                                                                                                                                                                                                                                                                                                                                          |
| <code>id</code>     | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.                                                   |

|                       |                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>idLabels</code> | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor. |
| <code>grid</code>     | an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xyplot</code> defaults to TRUE, else defaults to FALSE.                                                                                                                                                                                   |
| <code>...</code>      | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                                           |

**Value**

a diagnostic Trellis plot for assessing normality of residuals.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
fm1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
 correlation = corAR1(form = ~ 1 | Mare))
qqnorm(fm1, abline = c(0,1))
```

**qqnorm.lme**

*Normal Plot of Residuals or Random Effects from an lme Object*

**Description**

Diagnostic plots for assessing the normality of residuals and random effects in the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

**Usage**

```
S3 method for class 'lme'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

**Arguments**

|                |                                                                                                                                                                                                                                                                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code> | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model or from class <code>lmlist</code> , representing a list of <code>lm</code> objects, or from class <code>lm</code> , representing a fitted linear model, or from class <code>nls</code> , representing a nonlinear least squares fitted model. |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>form</b>     | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <i>y</i> can be referenced. In addition, <i>y</i> itself can be referenced in the formula using the symbol ". ". Conditional expressions on the right of a   operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <i>form</i> and to the left of a   operator must evaluate to a residuals vector, or a random effects matrix. Default is ~ resid(., type = "p"), corresponding to a normal plot of the standardized residuals evaluated at the innermost level of nesting. |
| <b>abline</b>   | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.                                                                                                                                                                                                                                                                                                                                                           |
| <b>id</b>       | an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <i>idLabels</i> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.                                                          |
| <b>idLabels</b> | an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <i>id</i> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.                                                                                                                                                                                                                                                                                            |
| <b>grid</b>     | an optional logical value indicating whether a grid should be added to plot. Default is FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>...</b>      | optional arguments passed to the Trellis plot function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Value

a diagnostic Trellis plot for assessing normality of residuals or random effects.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Quinidine*****Quinidine Kinetics***

---

**Description**

The Quinidine data frame has 1471 rows and 14 columns.

**Format**

This data frame contains the following columns:

- Subject** a factor identifying the patient on whom the data were collected.
- time** a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.
- conc** a numeric vector giving the serum quinidine concentration (mg/L).
- dose** a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.
- interval** a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.
- Age** a numeric vector giving the age of the subject on entry to the study (yr).
- Height** a numeric vector giving the height of the subject on entry to the study (in.).
- Weight** a numeric vector giving the body weight of the subject (kg).
- Race** a factor with levels Caucasian, Latin, and Black identifying the race of the subject.
- Smoke** a factor with levels no and yes giving smoking status at the time of the measurement.
- Ethanol** a factor with levels none, current, former giving ethanol (alcohol) abuse status at the time of the measurement.
- Heart** a factor with levels No/Mild, Moderate, and Severe indicating congestive heart failure for the subject.
- Creatinine** an ordered factor with levels < 50 <>= 50 indicating the creatine clearance (mg/min).
- glyco** a numeric vector giving the alpha-1 acid glycoprotein concentration (mg/dL). Often measured at the same time as the quinidine concentration.

**Details**

Verme et al. (1992) analyze routine clinical data on patients receiving the drug quinidine as a treatment for cardiac arrhythmia (atrial fibrillation or ventricular arrhythmias). All patients were receiving oral quinidine doses. At irregular intervals blood samples were drawn and serum concentrations of quinidine were determined. These data are analyzed in several publications, including Davidian and Giltinan (1995, section 9.3).

---

**quinModel***Model function for the Quinidine data*

---

## Description

A model function for a model used with the Quinidine data. This function calls compiled C code.

## Usage

```
quinModel(Subject, time, conc, dose, interval, lV, lKa, lCl)
```

## Arguments

|          |                                                                                                                                                                                                                                       |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Subject  | a factor identifying the patient on whom the data were collected.                                                                                                                                                                     |
| time     | a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.                                                                     |
| conc     | a numeric vector giving the serum quinidine concentration (mg/L).                                                                                                                                                                     |
| dose     | a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base. |
| interval | a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.                                                       |
| lV       | numeric. A vector of values of the natural log of the effective volume of distribution according to Subject and time.                                                                                                                 |
| lKa      | numeric. A vector of values of the natural log of the absorption rate constant according to Subject and time.                                                                                                                         |
| lCl      | numeric. A vector of values of the natural log of the clearance parameter according to Subject and time.                                                                                                                              |

## Details

See the details section of [Quinidine](#) for a description of the model function that *quinModel* evaluates.

## Value

a numeric vector of predicted quinidine concentrations.

**Rail***Evaluation of Stress in Railway Rails*

---

**Description**

The Rail data frame has 18 rows and 2 columns.

**Format**

This data frame contains the following columns:

**Rail** an ordered factor identifying the rail on which the measurement was made.

**travel** a numeric vector giving the travel time for ultrasonic head-waves in the rail (nanoseconds).  
The value given is the original travel time minus 36,100 nanoseconds.

**Details**

Devore (2000, Example 10.10, p. 427) cites data from an article in *Materials Evaluation* on “a study of travel time for a certain type of wave that results from longitudinal stress of rails used for railroad track.”

**random.effects***Extract Random Effects*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmlist` and `lme`.

**Usage**

```
random.effects(object, ...)
ranef(object, ...)
```

**Arguments**

`object` any fitted model object from which random effects estimates can be extracted.  
`...` some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

## References

```

**ranef.lme**

*Extract lme Random Effects*

## Description

The estimated random effects at level  $i$  are represented as a data frame with rows given by the different groups at that level and columns given by the random effects. If a single level of grouping is specified, the returned object is a data frame; else, the returned object is a list of such data frames. Optionally, the returned data frame(s) may be augmented with covariates summarized over groups.

## Usage

```
S3 method for class 'lme'
ranef(object, augFrame, level, data, which, FUN,
 standard, omitGroupingFactor, subset, ...)
```

## Arguments

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b>   | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>augFrame</b> | an optional logical value. If TRUE, the returned data frame is augmented with variables defined in <code>data</code> ; else, if FALSE, only the coefficients are returned. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                         |
| <b>level</b>    | an optional vector of positive integers giving the levels of grouping to be used in extracting the random effects from an object with multiple nested grouping levels. Defaults to all levels of grouping.                                                                                                                                                                                                                                                                                                                            |
| <b>data</b>     | an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit <code>object</code> .                                                                                                                                                                                                                                                                                                                                          |
| <b>which</b>    | an optional positive integer vector specifying which columns of <code>data</code> should be used in the augmentation of the returned data frame. Defaults to all columns in <code>data</code> .                                                                                                                                                                                                                                                                                                                                       |
| <b>FUN</b>      | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing <code>data</code> by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame such as |

ordered, factor, or numeric. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.

|                    |                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| standard           | an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the estimate of the standard deviation of that group of random effects). Defaults to FALSE.                                     |
| omitGroupingFactor | an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of data but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE. |
| subset             | an optional expression indicating for which rows the random effects should be extracted.                                                                                                                                                            |
| ...                | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                           |

## Value

a data frame, or list of data frames, with the estimated random effects at the grouping level(s) specified in level and, optionally, other covariates summarized over groups. The returned object inherits from classes `random.effects.lme` and `data.frame`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. pp. 100, 461.

## See Also

`coef.lme`, `gsummary`, `lme`, `plot.ranef.lme`, `random.effects`

## Examples

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
ranef(fm1)
random.effects(fm1) # same as above
random.effects(fm1, augFrame = TRUE)
```

---

**ranef.lmList***Extract lmList Random Effects*

---

## Description

The difference between the individual `lm` components coefficients and their average is calculated.

## Usage

```
S3 method for class 'lmList'
ranef(object, augFrame, data, which, FUN, standard,
 omitGroupingFactor, ...)
```

## Arguments

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>             | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>augFrame</code>           | an optional logical value. If TRUE, the returned data frame is augmented with variables defined in <code>data</code> ; else, if FALSE, only the coefficients are returned. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>data</code>               | an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit <code>object</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>which</code>              | an optional positive integer vector specifying which columns of <code>data</code> should be used in the augmentation of the returned data frame. Defaults to all columns in <code>data</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>FUN</code>                | an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable. |
| <code>standard</code>           | an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the corresponding estimated standard error). Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>omitGroupingFactor</code> | an optional logical value. When TRUE the grouping factor itself will be omitted from the group-wise summary of <code>data</code> but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>...</code>                | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

RatPupWeight                    *The weight of rat pups*

---

**Description**

The RatPupWeight data frame has 322 rows and 5 columns.

**Format**

This data frame contains the following columns:

**weight** a numeric vector

**sex** a factor with levels Male Female

**Litter** an ordered factor with levels 9 < 8 < 7 < 4 < 2 < 10 < 1 < 3 < 5 < 6 < 21 < 22 < 24 < 27 < 26 < 25 < 23 < 17 < 11 < 14 < 13 < 15 < 16 < 20 < 19 < 18 < 12

**Lsize** a numeric vector

**Treatment** an ordered factor with levels Control < Low < High

**recalc***Recalculate Condensed Linear Model Object*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, `modelStruct`, `reStruct`, and `varFunc`.

**Usage**

```
recalc(object, conLin, ...)
```

**Arguments**

- |        |                                                                                                                                                                                                                                      |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | any object which induces a recalculation of the condensed linear model object <code>conLin</code> .                                                                                                                                  |
| conLin | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. |
| ...    | some methods for this generic can take additional arguments.                                                                                                                                                                         |

**Value**

the recalculated condensed linear model object.

**Note**

This function is only used inside model fitting functions, such as `lme` and `gls`, that require recalculation of a condensed linear model object.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

```

---

**recalc.corStruct***Recalculate for corStruct Object*

---

**Description**

This method function pre-multiples the "Xy" component of `conLin` by the transpose square-root factor(s) of the correlation matrix (matrices) associated with `object` and adds the log-likelihood contribution of `object`, given by `logLik(object)`, to the "logLik" component of `conLin`.

**Usage**

```
S3 method for class 'corStruct'
recalc(object, conLin, ...)
```

**Arguments**

- |                     |                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>corStruct</code> , representing a correlation structure.                                                                                                                                       |
| <code>conLin</code> | a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                            |

**Value**

the recalculated condensed linear model object.

**Note**

This method function is only used inside model fitting functions, such as `lme` and `gls`, that allow correlated error terms.

## Description

The log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)` is calculated and added to the `logLik` component of `conLin`. The `settings` attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods for the (restricted) log-likelihood calculations are described in Bates and Pinheiro (1998).

## Usage

```
S3 method for class 'reStruct'
recalc(object, conLin, ...)
```

## Arguments

- |                     |                                                                                                                                                                                                                                                                    |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>reStruct</code> , representing a random effects structure and consisting of a list of <code>pdMat</code> objects.                                                                                                            |

## Description

This method function pre-multiples the "Xy" component of `conLin` by a diagonal matrix with diagonal elements given by the weights corresponding to the variance structure represented by `object` and adds the log-likelihood contribution of `object`, given by `logLik(object)`, to the "logLik" component of `conLin`.

**Usage**

```
S3 method for class 'varFunc'
recalc(object, conLin, ...)
```

**Arguments**

- object** an object inheriting from class `varFunc`, representing a variance function structure.
- conLin** a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
- ...** some methods for this generic require additional arguments. None are used in this method.

**Value**

the recalculated condensed linear model object.

**Note**

This method function is only used inside model fitting functions, such as `lme` and `gls`, that allow heteroscedastic error terms.

**residuals.gls***Extract gls Residuals*

---

## Description

The residuals for the linear model represented by object are extracted.

## Usage

```
S3 method for class 'gls'
residuals(object, type, ...)
```

**Arguments**

- object** an object inheriting from class `gls`, representing a generalized least squares fitted linear model, or from class `gnls`, representing a generalized nonlinear least squares fitted linear model.
- type** an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "response".
- ... some methods for this generic function require additional arguments. None are used in this method.

**Value**

a vector with the residuals for the linear model represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

 correlation = corAR1(form = ~ 1 | Mare))
residuals(fm1)
```

**residuals.glsStruct**    *Calculate glsStruct Residuals*

**Description**

The residuals for the linear model represented by `object` are extracted.

**Usage**

```
S3 method for class 'glsStruct'
residuals(object, glsFit, ...)
```

**Arguments**

- `object` an object inheriting from class `glsStruct`, representing a list of linear model components, such as `corStruct` and `varFunc` objects.
- `glsFit` an optional list with components `logLik` (log-likelihood), `beta` (coefficients), `sigma` (standard deviation for error term), `varBeta` (coefficients' covariance matrix), `fitted` (fitted values), and `residuals` (residuals). Defaults to `attr(object, "glsFit")`.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the residuals for the linear model represented by `object`.

**Note**

This method function is primarily used inside `gls` and `residuals.gls`.

`residuals.gnlsStruct` *Calculate gnlsStruct Residuals*

**Description**

The residuals for the nonlinear model represented by `object` are extracted.

**Usage**

```
S3 method for class 'gnlsStruct'
residuals(object, ...)
```

**Arguments**

- `object` an object inheriting from class `gnlsStruct`, representing a list of model components, such as `corStruct` and `varFunc` objects, and attributes specifying the underlying nonlinear model and the response variable.
- `...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the residuals for the nonlinear model represented by `object`.

**Note**

This method function is primarily used inside `gnls` and `residuals.gnls`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`gnls`, `residuals.gnls`, `fitted.gnlsStruct`

`residuals.lme`

*Extract lme Residuals*

**Description**

The residuals at level  $i$  are obtained by subtracting the fitted levels at that level from the response vector (and dividing by the estimated within-group standard error, if `type="pearson"`). The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ .

**Usage**

```
S3 method for class 'lme'
residuals(object, level, type, asList, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>level</code>  | an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population residuals. Defaults to the highest or innermost level of grouping.                                                                                                                                                                                                                                                    |
| <code>type</code>   | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson". |
| <code>asList</code> | an optional logical value. If TRUE and a single value is given in <code>level</code> , the returned object is a list with the residuals split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> . Defaults to FALSE.                                                                                                                                                                                                                                                                        |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Value**

if a single level of grouping is specified in `level`, the returned value is either a list with the residuals split by groups (`asList = TRUE`) or a vector with the residuals (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the residuals at different levels and the grouping factors. For a vector or data frame result the `naresid` method is applied.

fm1 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
residuals(fm1, level = 0:1)
```

`residuals.lmeStruct`     *Calculate lmeStruct Residuals*

**Description**

The residuals at level  $i$  are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ .

**Usage**

```
S3 method for class 'lmeStruct'
residuals(object, level, conLin, lmeFit, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>lmeStruct</code> , representing a list of linear mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.                                                                                                                                                             |
| <code>level</code>  | an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.                                                               |
| <code>conLin</code> | an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying <code>lme</code> model. Defaults to <code>attr(object, "conLin")</code> . |
| <code>lmeFit</code> | an optional list with components <code>beta</code> and <code>b</code> containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the residuals. Defaults to <code>attr(object, "lmeFit")</code> .                                                                                                                           |
| <code>...</code>    | some methods for this generic accept optional arguments.                                                                                                                                                                                                                                                                                                                      |

**Value**

if a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

**Note**

This method function is primarily used within the `lme` function.

`residuals.lmList`      *Extract lmList Residuals*

**Description**

The residuals are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

**Usage**

```
S3 method for class 'lmList'
residuals(object, type, subset, asList, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>subset</code> | an optional character or integer vector naming the <code>lm</code> components of <code>object</code> from which the residuals are to be extracted. Default is <code>NULL</code> , in which case all components are used.                                                                                                                                                                                                                                                                                                                                    |
| <code>type</code>   | an optional character string specifying the type of residuals to be extracted. Options include "response" for the "raw" residuals (observed - fitted), "pearson" for the standardized residuals (raw residuals divided by the estimated residual standard error) using different standard errors for each <code>lm</code> fit, and "pooled.pearson" for the standardized residuals using a pooled estimate of the residual standard error. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "response". |
| <code>asList</code> | an optional logical value. If <code>TRUE</code> , the returned object is a list with the residuals split by groups; else the returned value is a vector. Defaults to <code>FALSE</code> .                                                                                                                                                                                                                                                                                                                                                                   |
| ...                 | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Value**

a list with components given by the residuals of each `lm` component of `object`, or a vector with the residuals for all `lm` components of `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`lmList`, `fitted.lmList`

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
residuals(fm1)
```

`residuals.nlmeStruct`    *Calculate nlmeStruct Residuals*

**Description**

The residuals at level  $i$  are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters.

**Usage**

```
S3 method for class 'nlmeStruct'
residuals(object, level, conLin, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>nlmeStruct</code> , representing a list of mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.                                                                                                                                                                    |
| <code>level</code>  | an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.                                                                |
| <code>conLin</code> | an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying <code>nlme</code> model. Defaults to <code>attr(object, "conLin")</code> . |
| <code>...</code>    | optional arguments to the <code>residuals</code> generic. Not used.                                                                                                                                                                                                                                                                                                            |

**Value**

if a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

**Note**

This method function is primarily used within the `nlme` function.

**Author(s)**

`reStruct`

*Random Effects Structure*

**Description**

This function is a constructor for the `reStruct` class, representing a random effects structure and consisting of a list of `pdMat` objects, plus a `settings` attribute containing information for the optimization algorithm used to fit the associated mixed-effects model.

**Usage**

```
reStruct(object, pdClass, REML, data)
S3 method for class 'reStruct'
print(x, sigma, reEstimates, verbose, ...)
```

**Arguments**

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>  | any of the following: (i) a one-sided formula of the form $\sim x_1 + \dots + x_n   g_1 / \dots / g_m$ , with $x_1 + \dots + x_n$ specifying the model for the random effects and $g_1 / \dots / g_m$ the grouping structure ( $m$ may be equal to 1, in which case no $/$ is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form $\sim x_1 + \dots + x_n   g$ , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form $\sim x_1 + \dots + x_n$ , or a <code>pdMat</code> object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or <code>pdMat</code> objects. In this case, the grouping structure formula will be derived from the data used to fit the mixed-effects model, which should inherit from class <code>groupedData</code> ; (iv) a named list of formulas or <code>pdMat</code> objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an <code>reStruct</code> object. |
| <code>pdClass</code> | an optional character string with the name of the <code>pdMat</code> class to be used for the formulas in <code>object</code> . Defaults to "pdSymm" which corresponds to a general positive-definite matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|             |                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REML        | an optional logical value. If TRUE, the associated mixed-effects model will be fitted using restricted maximum likelihood; else, if FALSE, maximum likelihood will be used. Defaults to FALSE.                                                                                                                                                                                                       |
| data        | an optional data frame in which to evaluate the variables used in the random effects formulas in object. It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying pdMat objects. If NULL, no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called. |
| x           | an object inheriting from class reStruct to be printed.                                                                                                                                                                                                                                                                                                                                              |
| sigma       | an optional numeric value used as a multiplier for the square-root factors of the pdMat components (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.                                                                                                                                                                                                |
| reEstimates | an optional list with the random effects estimates for each level of grouping. Only used when verbose = TRUE.                                                                                                                                                                                                                                                                                        |
| verbose     | an optional logical value determining if the random effects estimates should be printed. Defaults to FALSE.                                                                                                                                                                                                                                                                                          |
| ...         | Optional arguments can be given to other methods for this generic. None are used in this method.                                                                                                                                                                                                                                                                                                     |

**Value**

an object inheriting from class reStruct, representing a random effects structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[groupedData](#), [lme](#), [pdMat](#), [solve.reStruct](#), [summary.reStruct](#), [update.reStruct](#)

**Examples**

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
rs1
```

**Description**

The model object is fit to the data. Using the fitted values of the parameters, nsim new data vectors from this model are simulated. Both m1 and m2 are fit by maximum likelihood (ML) and/or by restricted maximum likelihood (REML) to each of the simulated data vectors.

**Usage**

```
S3 method for class 'lme'
simulate(object, nsim, seed, m2, method, niterEM, useGen, ...)
```

## Arguments

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object               | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model, or a list containing an <code>lme</code> model specification. If given as a list, it should contain components <code>fixed</code> , <code>data</code> , and <code>random</code> with values suitable for a call to <code>lme</code> . This argument defines the null model.                                                                                                                                                                |
| <code>m2</code>      | an <code>lme</code> object, or a list, like <code>m1</code> containing a second <code>lme</code> model specification. This argument defines the alternative model. If given as a list, only those parts of the specification that change between model <code>m1</code> and <code>m2</code> need to be specified.                                                                                                                                                                                                                                |
| <code>seed</code>    | an optional integer that is passed to <code>set.seed</code> . Defaults to a random integer.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>method</code>  | an optional character array. If it includes "REML" the models are fit by maximizing the restricted log-likelihood. If it includes "ML" the log-likelihood is maximized. Defaults to <code>c("REML", "ML")</code> , in which case both methods are used.                                                                                                                                                                                                                                                                                         |
| <code>nsim</code>    | an optional positive integer specifying the number of simulations to perform. Defaults to <b>1</b> . <b>This has changed. Previously the default was 1000.</b>                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>niterEM</code> | an optional integer vector of length 2 giving the number of iterations of the EM algorithm to apply when fitting the <code>m1</code> and <code>m2</code> to each simulated set of data. Defaults to <code>c(40, 200)</code> .                                                                                                                                                                                                                                                                                                                   |
| <code>useGen</code>  | an optional logical value. If TRUE, numerical derivatives are used to obtain the gradient and the Hessian of the log-likelihood in the optimization algorithm in the <code>ms</code> function. If FALSE, the default algorithm in <code>ms</code> for functions that do not incorporate gradient and Hessian attributes is used. Default depends on the <code>pdMat</code> classes used in <code>m1</code> and <code>m2</code> : if both are standard classes (see <code>pdClasses</code> ) then defaults to TRUE, otherwise defaults to FALSE. |
| ...                  | optional additional arguments. None are used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Value

an object of class `simulate.lme` with components `null` and `alt`. Each of these has components `ML` and/or `REML` which are matrices. An attribute called `Random.seed` contains the seed that was used for the random number generator.

## Author(s)

**solve.pdMat***Calculate Inverse of a Positive-Definite Matrix*

---

**Description**

The positive-definite matrix represented by *a* is inverted and assigned to *a*.

**Usage**

```
S3 method for class 'pdMat'
solve(a, b, ...)
```

**Arguments**

- a* an object inheriting from class *pdMat*, representing a positive definite matrix.
- b* this argument is only included for consistency with the generic function and is not used in this method function.
- ... some methods for this generic require additional arguments. None are used in this method.

**Value**

a *pdMat* object similar to *a*, but with coefficients corresponding to the inverse of the positive-definite matrix represented by *a*.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

|                             |                                          |
|-----------------------------|------------------------------------------|
| <code>solve.reStruct</code> | <i>Apply Solve to an reStruct Object</i> |
|-----------------------------|------------------------------------------|

---

## Description

Solve is applied to each pdMat component of `a`, which results in inverting the positive-definite matrices they represent.

## Usage

```
S3 method for class 'reStruct'
solve(a, b, ...)
```

## Arguments

- `a` an object inheriting from class `reStruct`, representing a random effects structure and consisting of a list of `pdMat` objects.
- `b` this argument is only included for consistency with the generic function and is not used in this method function.
- `...` some methods for this generic require additional arguments. None are used in this method.

## Value

an `reStruct` object similar to `a`, but with the `pdMat` components representing the inverses of the matrices represented by the components of `a`.

|         |                                 |
|---------|---------------------------------|
| Soybean | <i>Growth of soybean plants</i> |
|---------|---------------------------------|

---

## Description

The Soybean data frame has 412 rows and 5 columns.

## Format

This data frame contains the following columns:

**Plot** a factor giving a unique identifier for each plot.

**Variety** a factor indicating the variety; Forrest (F) or Plant Introduction \#416937 (P).

**Year** a factor indicating the year the plot was planted.

**Time** a numeric vector giving the time the sample was taken (days after planting).

**weight** a numeric vector giving the average leaf weight per plant (g).

## Details

These data are described in Davidian and Giltinan (1995, 1.1.3, p.7) as “Data from an experiment to compare growth patterns of two genotypes of soybeans: Plant Introduction \#416937 (P), an experimental strain, and Forrest (F), a commercial variety.”

|--------------|------------------------|
| splitFormula | <i>Split a Formula</i> |
|--------------|------------------------|

---

## Description

Splits the right hand side of form into a list of subformulas according to the presence of sep. The left hand side of form, if present, will be ignored. The length of the returned list will be equal to the number of occurrences of sep in form plus one.

## Usage

```
splitFormula(form, sep)
```

**Arguments**

- form** a formula object.  
**sep** an optional character string specifying the separator to be used for splitting the formula. Defaults to "/".

**Value**

a list of formulas, corresponding to the split of **form** according to **sep**.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
splitFormula(~ g1/g2/g3)
```

**Description**

The Spruce data frame has 1027 rows and 4 columns.

**Format**

This data frame contains the following columns:

- Tree** a factor giving a unique identifier for each tree.  
**days** a numeric vector giving the number of days since the beginning of the experiment.  
**logSize** a numeric vector giving the logarithm of an estimate of the volume of the tree trunk.  
**plot** a factor identifying the plot in which the tree was grown.

**Details**

Diggle, Liang, and Zeger (1994, Example 1.3, page 5) describe data on the growth of spruce trees that have been exposed to an ozone-rich atmosphere or to a normal atmosphere.

---

summary.corStruct      *Summarize a corStruct Object*

---

## Description

This method function prepares object to be printed using the `print.summary` method, by changing its class and adding a `structName` attribute to it.

## Usage

```
S3 method for class 'corStruct'
summary(object, structName, ...)
```

## Arguments

- |            |                                                                                                                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object     | an object inheriting from class <code>corStruct</code> , representing a correlation structure.                                                                                                                 |
| structName | an optional character string defining the type of correlation structure associated with <code>object</code> , to be used in the <code>print.summary</code> method. Defaults to <code>class(object)[1]</code> . |
| ...        | some methods for this generic require additional arguments. None are used in this method.                                                                                                                      |

## Value

an object identical to `object`, but with its class changed to `summary.corStruct` and an additional attribute `structName`. The returned value inherits from the same classes as `object`.

## Author(s)

José Pinheiro and Douglas Bates

```
cs1 <- corAR1(0.2)
summary(cs1)
```

---

**summary.gls***Summarize a gls Object*

---

**Description**

Additional information about the linear model fit represented by object is extracted and included as components of object.

**Usage**

```
S3 method for class 'gls'
summary(object, verbose, ...)
```

**Arguments**

- |         |                                                                                                                  |
|---------|------------------------------------------------------------------------------------------------------------------|
| object  | an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model. |
| verbose | an optional logical value used to control the amount of output when the object is printed. Defaults to FALSE.    |
| ...     | some methods for this generic require additional arguments. None are used in this method.                        |

**Value**

an object inheriting from class `summary.gls` with all components included in `object` (see [glsObject](#) for a full description of the components) plus the following components:

- |           |                                                                                                                                                                                                                                                                                                                                  |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| corBeta   | approximate correlation matrix for the coefficients estimates                                                                                                                                                                                                                                                                    |
| tTable    | a data frame with columns Value, Std. Error, t-value, and p-value representing respectively the coefficients estimates, their approximate standard errors, the ratios between the estimates and their standard errors, and the associated p-value under a <i>t</i> approximation. Rows correspond to the different coefficients. |
| residuals | if more than five observations are used in the <code>gls</code> fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the residuals distribution; else the residuals.                                                                                                                           |
| AIC       | the Akaike Information Criterion corresponding to <code>object</code> .                                                                                                                                                                                                                                                          |
| BIC       | the Bayesian Information Criterion corresponding to <code>object</code> .                                                                                                                                                                                                                                                        |

summary(fm1)
```

---

**summary.lme***Summarize an lme Object*

---

**Description**

Additional information about the linear mixed-effects fit represented by `object` is extracted and included as components of `object`. The returned object is suitable for printing with the `print.summary.lme` method.

**Usage**

```
S3 method for class 'lme'
summary(object, adjustSigma, verbose, ...)
```

**Arguments**

- |                          |                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>      | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                  |
| <code>adjustSigma</code> | an optional logical value. If TRUE and the estimation method used to obtain <code>object</code> was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE. |
| <code>verbose</code>     | an optional logical value used to control the amount of output in the <code>print.summary.lme</code> method. Defaults to FALSE.                                                                                                                                                                                                                       |
| <code>...</code>         | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                             |

**Value**

an object inheriting from class `summary.lme` with all components included in `object` (see [lmeObject](#) for a full description of the components) plus the following components:

- |                        |                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>corFixed</code>  | approximate correlation matrix for the fixed effects estimates                                                                                                                                                                                                                                                                                                    |
| <code>tTable</code>    | a data frame with columns Value, Std. Error, DF, t-value, and p-value representing respectively the fixed effects estimates, their approximate standard errors, the denominator degrees of freedom, the ratios between the estimates and their standard errors, and the associated p-value from a t distribution. Rows correspond to the different fixed effects. |
| <code>residuals</code> | if more than five observations are used in the <code>lme</code> fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the innermost grouping level residuals distribution; else the innermost grouping level residuals.                                                                                                          |
| <code>AIC</code>       | the Akaike Information Criterion corresponding to <code>object</code> .                                                                                                                                                                                                                                                                                           |
| <code>BIC</code>       | the Bayesian Information Criterion corresponding to <code>object</code> .                                                                                                                                                                                                                                                                                         |

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[AIC](#), [BIC](#), [lme](#), [print.summary.lme](#)

**Examples**

```
fm1 <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
summary(fm1)
```

**summary.lmList**

*Summarize an lmList Object*

**Description**

The `summary.lm` method is applied to each `lm` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.lmList` method.

**Usage**

```
S3 method for class 'lmList'
summary(object, pool, ...)
```

**Arguments**

- |                     |                                                                                                                                                              |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> fitted objects.                                                 |
| <code>pool</code>   | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> . |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.                                                                    |

**Value**

a list with summary statistics obtained by applying `summary.lm` to the elements of `object`, inheriting from class `summary.lmList`. The components of `value` are:

- |                           |                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>call</code>         | a list containing an image of the <code>lmList</code> call that produced <code>object</code> .                                                                                                                                                                                                                                                                                                                                    |
| <code>coefficients</code> | a three dimensional array with summary information on the <code>lm</code> coefficients. The first dimension corresponds to the names of the object components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(> t )", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names. |
| <code>correlation</code>  | a three dimensional array with the correlations between the individual <code>lm</code> coefficient estimates. The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by <code>lm</code> component.                  |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cov.unscaled | a three dimensional array with the unscaled variances/covariances for the individual lm coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by lm component. |
| df           | an array with the number of degrees of freedom for the model and for residuals, for each lm component.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| df.residual  | the total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all lm components.                                                                                                                                                                                                                                                                                                                                                                                                           |
| fstatistics  | an array with the F test statistics and corresponding degrees of freedom, for each lm component.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| pool         | the value of the pool argument to the function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| r.squared    | a vector with the multiple R-squared statistics for each lm component.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| residuals    | a list with components given by the residuals from individual lm fits.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| RSE          | the pooled estimate of the residual standard error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| sigma        | a vector with the residual standard error estimates for the individual lm fits.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| terms        | the terms object used in fitting the individual lm components.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
summary(fm1)
```

**summary.modelStruct**     *Summarize a modelStruct Object*

**Description**

This method function applies `summary` to each element of object.

**Usage**

```
S3 method for class 'modelStruct'
summary(object, ...)
```

**Arguments**

|        |                                                                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>modelStruct</code> , representing a list of model components, such as <code>reStruct</code> , <code>corStruct</code> and <code>varFunc</code> objects. |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                    |

**Value**

a list with elements given by the summarized components of object. The returned value is of class `summary.modelStruct`, also inheriting from the same classes as object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[reStruct](#), [summary](#)

**Examples**

```
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
 corStruct = corAR1(0.3))
summary(lms1)
```

**summary.nlsList**

*Summarize an nlsList Object*

**Description**

The `summary` function is applied to each `nls` component of object to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.nlsList` method.

**Usage**

```
S3 method for class 'nlsList'
summary(object, ...)
```

**Arguments**

|                     |                                                                                                                                                                                                                                                                    |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>nlsList</code> , representing a list of <code>nls</code> fitted objects.                                                                                                                                                     |
| <code>...</code>    | optional arguments to the <code>summary.lmList</code> method. One such optional argument is <code>pool</code> , a logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> . |

**Value**

a list with summary statistics obtained by applying `summary` to the elements of `object`, inheriting from class `summary.nlsList`. The components of `value` are:

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>call</code>       | a list containing an image of the <code>nlsList</code> call that produced <code>object</code> .                                                                                                                                                                                                                                                                                                                                    |
| <code>parameters</code> | a three dimensional array with summary information on the <code>nls</code> coefficients. The first dimension corresponds to the names of the object components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(> t )", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names. |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| correlation  | a three dimensional array with the correlations between the individual nls coefficient estimates. The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by nls component.                                                                                                                                        |
| cov.unscaled | a three dimensional array with the unscaled variances/covariances for the individual lm coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the object components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by nls component. |
| df           | an array with the number of degrees of freedom for the model and for residuals, for each nls component.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| df.residual  | the total number of degrees of freedom for residuals, corresponding to the sum of residuals df of all nls components.                                                                                                                                                                                                                                                                                                                                                                                                           |
| pool         | the value of the pool argument to the function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| RSE          | the pooled estimate of the residual standard error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| sigma        | a vector with the residual standard error estimates for the individual lm fits.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Examples**

```
fm1 <- nlsList(SSasymp, Loblolly)
summary(fm1)
```

summary.pdMat

*Summarize a pdMat Object*

**Description**

Attributes structName and noCorrelation, with the values of the corresponding arguments to the method function, are appended to object and its class is changed to `summary.pdMat`.

**Usage**

```
S3 method for class 'pdMat'
summary(object, structName, noCorrelation, ...)
```

**Arguments**

- object** an object inheriting from class `pdMat`, representing a positive definite matrix.
- structName** an optional character string with a description of the `pdMat` class. Default depends on the method function: "Blocked" for `pdBlocked`, "Compound Symmetry" for `pdCompSymm`, "Diagonal" for `pdDiag`, "Multiple of an Identity" for `pdIdent`, "General Positive-Definite, Natural Parametrization" for `pdNatural`, "General Positive-Definite" for `pdSymm`, and `data.class(object)` for `pdMat`.
- noCorrelation** an optional logical value indicating whether correlations are to be printed in `print.summary.pdMat`. Default depends on the method function: FALSE for `pdDiag` and `pdIdent`, and TRUE for all other classes.
- ...** some methods for this generic require additional arguments. None are used in this method.

**Value**

an object similar to `object`, with additional attributes `structName` and `noCorrelation`, inheriting from class `summary.pdMat`.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**Examples**

```
summary(pdSymm(diag(4)))
```

**summary.varFunc**      *Summarize varFunc Object*

**Description**

A `structName` attribute, with the value of corresponding argument, is appended to `object` and its class is changed to `summary.varFunc`.

**Usage**

```
S3 method for class 'varFunc'
summary(object, structName, ...)
```

### Arguments

|            |                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object     | an object inheriting from class varFunc, representing a variance function structure.                                                                                                                                                                                                                                                                                                                           |
| structName | an optional character string with a description of the varFunc class. Default depends on the method function: "Combination of variance functions" for varComb, "Constant plus power of covariate" for varConstPower, "Exponential of variance covariate" for varExp, "Different standard deviations per stratum" for varIdent, "Power of variance covariate" for varPower, and data.class(object) for varFunc. |
| ...        | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                      |

### Value

an object similar to object, with an additional attribute structName, inheriting from class summary.varFunc.

```
vf1 <- varPower(0.3, form = ~age)
vf1 <- Initialize(vf1, Orthodont)
summary(vf1)
```

### Description

The Tetracycline1 data frame has 40 rows and 4 columns.

### Format

This data frame contains the following columns:

- conc** a numeric vector
- Time** a numeric vector
- Subject** an ordered factor with levels 5 < 3 < 2 < 4 < 1
- Formulation** a factor with levels tetrachel tetracyn

Tetracycline2

*Pharmacokinetics of tetracycline***Description**

The Tetracycline2 data frame has 40 rows and 4 columns.

**Format**

This data frame contains the following columns:

**conc** a numeric vector

**Time** a numeric vector

**Subject** an ordered factor with levels 4 < 5 < 2 < 1 < 3

**Formulation** a factor with levels Berkmycin tetracyclin

**Source**

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York.

update.modelStruct

*Update a modelStruct Object***Description**

This method function updates each element of object, allowing the access to data.

**Usage**

```
S3 method for class 'modelStruct'
update(object, data, ...)
```

**Arguments**

- |        |                                                                                                                                                                      |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>modelStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects. |
| data   | a data frame in which to evaluate the variables needed for updating the elements of object.                                                                          |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                            |

**Value**

an object similar to object (same class, length, and names), but with updated elements.

**Note**

This method function is primarily used within model fitting functions, such as `lme` and `gls`, that allow model components such as variance functions.

update.varFunc

*Update varFunc Object*

---

**Description**

If the `formula(object)` includes a `"."` term, representing a fitted object, the variance covariate needs to be updated upon completion of an optimization cycle (in which the variance function weights are kept fixed). This method function allows a reevaluation of the variance covariate using the current fitted object and, optionally, other variables in the original data.

**Usage**

```
S3 method for class 'varFunc'
update(object, data, ...)
```

**Arguments**

- |        |                                                                                                                                                                                                                                                      |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object | an object inheriting from class <code>varFunc</code> , representing a variance function structure.                                                                                                                                                   |
| data   | a list with a component named <code>"."</code> with the current version of the fitted object (from which fitted values, coefficients, and residuals can be extracted) and, if necessary, other variables used to evaluate the variance covariate(s). |
| ...    | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                            |

**Value**

if `formula(object)` includes a `"."` term, an `varFunc` object similar to `object`, but with the variance covariate reevaluated at the current fitted object value; else `object` is returned unchanged.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**varClasses***Variance Function Classes*

---

**Description**

Standard classes of variance function structures (`varFunc`) available in the `nlme` library. Covariates included in the variance function, denoted by variance covariates, may involve functions of the fitted model object, such as the fitted values and the residuals. Different coefficients may be assigned to the levels of a classification factor.

**Value**

Available standard classes ():

|                            |                                                                                                                       |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>varExp</code>        | exponential of a variance covariate.                                                                                  |
| <code>varPower</code>      | power of a variance covariate.                                                                                        |
| <code>varConstPower</code> | constant plus power of a variance covariate.                                                                          |
| <code>varIdent</code>      | constant variance(s), generally used to allow different variances according to the levels of a classification factor. |
| <code>varFixed</code>      | fixed weights, determined by a variance covariate.                                                                    |
| <code>varComb</code>       | combination of variance functions.                                                                                    |

**Note**

Users may define their own `varFunc` classes by specifying a constructor function and, at a minimum, methods for the functions `coef`, `coef<-`, and `initialize`. For examples of these functions, see the methods for class `varPower`.

**varComb***Combination of Variance Functions*

---

**Description**

This function is a constructor for the varComb class, representing a combination of variance functions. The corresponding variance function is equal to the product of the variance functions of the varFunc objects listed in ....

**Usage**

```
varComb(...)
```

**Arguments**

... objects inheriting from class varFunc representing variance function structures.

**Value**

a varComb object representing a combination of variance functions, also inheriting from class varFunc.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

**varConstPower***Constant Plus Power Variance Function*

---

**Description**

This function is a constructor for the varConstPower class, representing a constant plus power variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the constant plus power variance function is defined as  $\sigma^2(v) = (\theta_1 + |v|^{\theta_2})^2$ , where  $\theta_1, \theta_2$  are the variance function coefficients. When a grouping factor is present, different  $\theta_1, \theta_2$  are used for each factor level.

**Usage**

```
varConstPower(const, power, form, fixed)
```

**Arguments**

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| const, power | optional numeric vectors, or lists of numeric values, with, respectively, the coefficients for the constant and the power terms. Both arguments must have length one, unless a grouping factor is specified in form. If either argument has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in form. If a grouping factor is present in form and the argument has length one, its value will be assigned to all grouping levels. Only positive values are allowed for const. Default is numeric(0), which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).                                                                                                                                                                                                                                                                              |
| form         | an optional one-sided formula of the form $\sim v$ , or $\sim v \mid g$ , specifying a variance covariate v and, optionally, a grouping factor g for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ". . .", representing a fitted model object from which fitted values (fitted(.)) and residuals (resid(.)) can be extracted (this allows the variance covariate to be updated during the optimization of an objective function). When a grouping factor is present in form, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the * operator, as in $\sim v \mid g1 * g2 * g3$ . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to $\sim \text{fitted}(\cdot)$ representing a variance covariate given by the fitted values of a fitted model object and no grouping factor. |
| fixed        | an optional list with components const and/or power, consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in form, the components of fixed must have names identifying which coefficients are to be fixed. Coefficients included in fixed are not allowed to vary during the optimization of an objective function. Defaults to NULL, corresponding to no fixed coefficients.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Value**

a varConstPower object representing a constant plus power variance function structure, also inheriting from class varFunc.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
vf1 <- varConstPower(1.2, 0.2, form = ~age|Sex)
```

---

VarCorr

*Extract variance and correlation components*

---

## Description

This function calculates the estimated variances, standard deviations, and correlations between the random-effects terms in a linear mixed-effects model, of class `lme`, or a nonlinear mixed-effects model, of class `nlme`. The within-group error variance and standard deviation are also calculated.

## Usage

```
VarCorr(x, sigma, rdig)
```

## Arguments

- |                    |                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | a fitted model object, usually an object inheriting from class <code>lme</code> .                                |
| <code>sigma</code> | an optional numeric value used as a multiplier for the standard deviations. Default is 1.                        |
| <code>rdig</code>  | an optional integer value specifying the number of digits used to represent correlation estimates. Default is 3. |

## Value

a matrix with the estimated variances, standard deviations, and correlations for the random effects. The first two columns, named `Variance` and `StdDev`, give, respectively, the variance and the standard deviations. If there are correlation components in the random effects model, the third column, named `Corr`, and the remaining unnamed columns give the estimated correlations among random effects within the same level of grouping. The within-group error variance and standard deviation are included as the last row in the matrix.

fm1 <- lme(distance ~ age, data = Orthodont, random = ~age)
VarCorr(fm1)
```

**varExp***Exponential Variance Function***Description**

This function is a constructor for the `varExp` class, representing an exponential variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the exponential variance function is defined as  $\sigma^2(v) = \exp(2\theta v)$ , where  $\theta$  is the variance function coefficient. When a grouping factor is present, a different  $\theta$  is used for each factor level.

**Usage**

```
varExp(value, form, fixed)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code> | an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in <code>form</code> . If value has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in <code>form</code> . If a grouping factor is present in <code>form</code> and <code>value</code> has length one, its value will be assigned to all grouping levels. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).                                                                                                                                                                                                                                                                                                                                                                                |
| <code>form</code>  | an optional one-sided formula of the form $\sim v$ , or $\sim v \mid g$ , specifying a variance covariate $v$ and, optionally, a grouping factor $g$ for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using ". . .", representing a fitted model object from which fitted values ( <code>fitted(.)</code> ) and residuals ( <code>resid(.)</code> ) can be extracted (this allows the variance covariate to be updated during the optimization of an objective function). When a grouping factor is present in <code>form</code> , a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in $\sim v \mid g1 * g2 * g3$ . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to $\sim \text{fitted}(\cdot)$ representing a variance covariate given by the fitted values of a fitted model object and no grouping factor. |
| <code>fixed</code> | an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in <code>form</code> , <code>fixed</code> must have names identifying which coefficients are to be fixed. Coefficients included in <code>fixed</code> are not allowed to vary during the optimization of an objective function. Defaults to <code>NULL</code> , corresponding to no fixed coefficients.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Value**

a `varExp` object representing an exponential variance function structure, also inheriting from class `varFunc`.

vf1 <- varExp(0.2, form = ~age|Sex)
```

---

varFixed

*Fixed Variance Function*

---

**Description**

This function is a constructor for the `varFixed` class, representing a variance function with fixed variances. Letting  $v$  denote the variance covariate defined in `value`, the variance function  $\sigma^2(v)$  for this class is  $\sigma^2(v) = |v|$ . The variance covariate  $v$  is evaluated once at initialization and remains fixed thereafter. No coefficients are required to represent this variance function.

**Usage**

```
varFixed(value)
```

**Arguments**

`value` a one-sided formula of the form  $\sim v$  specifying a variance covariate  $v$ . Grouping factors are ignored.

**Value**

a `varFixed` object representing a fixed variance function structure, also inheriting from class `varFunc`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**Examples**

```
vf1 <- varFixed(~age)
```

**varFunc***Variance Function Structure***Description**

If *object* is a one-sided formula, it is used as the argument to *varFixed* and the resulting object is returned. Else, if *object* inherits from class *varFunc*, it is returned unchanged.

**Usage**

```
varFunc(object)
```

**Arguments**

|               |                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>object</i> | either an one-sided formula specifying a variance covariate, or an object inheriting from class <i>varFunc</i> , representing a variance function structure. |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Value**

an object from class *varFunc*, representing a variance function structure.

```

**varIdent***Constant Variance Function***Description**

This function is a constructor for the *varIdent* class, representing a constant variance function structure. If no grouping factor is present in *form*, the variance function is constant and equal to one, and no coefficients required to represent it. When *form* includes a grouping factor with  $M > 1$  levels, the variance function allows  $M$  different variances, one for each level of the factor. For identifiability reasons, the coefficients of the variance function represent the ratios between the variances and a reference variance (corresponding to a reference group level). Therefore, only  $M - 1$  coefficients are needed to represent the variance function. By default, if the elements in *value* are unnamed, the first group level is taken as the reference level.

**Usage**

```
varIdent(value, form, fixed)
```

**Arguments**

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| value | an optional numeric vector, or list of numeric values, with the variance function coefficients. If no grouping factor is present in form, this argument is ignored, as the resulting variance function contains no coefficients. If value has length one, its value is repeated for all coefficients in the variance function. If value has length greater than one, it must have length equal to the number of grouping levels minus one and names which identify its elements to the levels of the grouping factor. Only positive values are allowed for this argument. Default is numeric(0), which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one). |
| form  | an optional one-sided formula of the form $\sim v$ , or $\sim v \mid g$ , specifying a variance covariate v and, optionally, a grouping factor g for the coefficients. The variance covariate is ignored in this variance function. When a grouping factor is present in form, a different coefficient value is used for each of its levels less one reference level (see description section below). Several grouping variables may be simultaneously specified, separated by the * operator, like in $\sim v \mid g1 * g2 * g3$ . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to $\sim 1$ .                                                                              |
| fixed | an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. It must have names identifying which coefficients are to be fixed. Coefficients included in fixed are not allowed to vary during the optimization of an objective function. Defaults to NULL, corresponding to no fixed coefficients.                                                                                                                                                                                                                                                                                                                                                                      |

**Variogram***Calculate Semi-variogram***Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `default`, `gls` and `lme`. See the appropriate method documentation for a description of the arguments.

**Usage**

```
Variogram(object, distance, ...)
```

**Arguments**

- |                       |                                                                                                                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>   | a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.                                                                                                                                                                                      |
| <code>distance</code> | a numeric vector with the pairwise distances corresponding to the elements of <code>object</code> . The order of the elements in <code>distance</code> must correspond to the pairs $(1, 2), (1, 3), \dots, (n-1, n)$ , with $n$ representing the length of <code>object</code> , and must have length $n(n-1)/2$ . |
| <code>...</code>      | some methods for this generic function require additional arguments.                                                                                                                                                                                                                                                |

**Value**

will depend on the method function used; see the appropriate documentation.

**Variogram.corExp***Calculate Semi-variogram for a corExp Object*

---

**Description**

This method function calculates the semi-variogram values corresponding to the Exponential correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

**Usage**

```
S3 method for class 'corExp'
Variogram(object, distance, sig2, length.out, ...)
```

**Arguments**

|            |                                                                                                                                                                                                                                        |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object     | an object inheriting from class corExp, representing an exponential spatial correlation structure.                                                                                                                                     |
| distance   | an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used. |
| sig2       | an optional numeric value representing the process variance. Defaults to 1.                                                                                                                                                            |
| length.out | an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.                                                                            |
| ...        | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                              |

**Value**

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

Variogram.corLin      *Calculate Semi-variogram for a corLin Object*

---

## Description

This method function calculates the semi-variogram values corresponding to the Linear correlation model, using the estimated coefficients corresponding to object, at the distances defined by distance.

## Usage

```
S3 method for class 'corLin'
Variogram(object, distance, sig2, length.out, ...)
```

## Arguments

|            |                                                                                                                                                                                                                                        |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object     | an object inheriting from class corLin, representing an Linear spatial correlation structure.                                                                                                                                          |
| distance   | an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used. |
| sig2       | an optional numeric value representing the process variance. Defaults to 1.                                                                                                                                                            |
| length.out | an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.                                                                            |
| ...        | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                              |

## Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

---

**Variogram.default**      *Calculate Semi-variogram*

---

**Description**

This method function calculates the semi-variogram for an arbitrary vector object, according to the distances in `distance`. For each pair of elements  $x, y$  in `object`, the corresponding semi-variogram is  $(x - y)^2/2$ . The semi-variogram is useful for identifying and modeling spatial correlation structures in observations with constant expectation and constant variance.

**Usage**

```
Default S3 method:
Variogram(object, distance, ...)
```

**Arguments**

- |                       |                                                                                                                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>   | a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.                                                                                                                                                                                      |
| <code>distance</code> | a numeric vector with the pairwise distances corresponding to the elements of <code>object</code> . The order of the elements in <code>distance</code> must correspond to the pairs $(1, 2), (1, 3), \dots, (n-1, n)$ , with $n$ representing the length of <code>object</code> , and must have length $n(n-1)/2$ . |
| <code>...</code>      | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                           |

**Value**

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

**Examples**

```
Not run:
fm1 <- lm(follicles ~ sin(2 * pi * Time) + cos(2 * pi * Time), Ovary,
 subset = Mare == 1)
Variogram(resid(fm1), dist(1:29))[1:10,]

End(Not run)
```

**Variogram.gls***Calculate Semi-variogram for Residuals from a gls Object***Description**

This method function calculates the semi-variogram for the residuals from a `gls` fit. The semi-variogram values are calculated for pairs of residuals within the same group level, if a grouping factor is present. If `collapse` is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (`robust = TRUE`) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

**Usage**

```
S3 method for class 'gls'
Variogram(object, distance, form, resType, data,
 na.action, maxDist, length.out, collapse, nint, breaks,
 robust, metric, ...)
```

**Arguments**

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | an object inheriting from class <code>gls</code> , representing a generalized least squares fitted model.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>distance</code>  | an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments <code>form</code> , <code>data</code> , and <code>metric</code> , unless <code>object</code> includes a <code>corSpatial</code> element, in which case the associated covariate (obtained with the <code>getCovariate</code> method) is used.                                                         |
| <code>form</code>      | an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a <code> </code> operator in <code>form</code> ). Default is <code>~1</code> , implying that the observation order within the groups is used to obtain the distances.                                                                                                                                                                          |
| <code>resType</code>   | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals ( <code>observed - fitted</code> ) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson". |
| <code>data</code>      | an optional data frame in which to interpret the variables in <code>form</code> . By default, the same data used to fit <code>object</code> is used.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>na.action</code> | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes an error message to be printed and the function to terminate, if there are any incomplete observations.                                                                                                                                                                                                                                                                                                                                            |
| <code>maxDist</code>   | an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.                                                                                                                                                                                                                                                                                                                                                                                                                 |

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| length.out | an optional integer value. When object includes a corSpatial element, its semi-variogram values are calculated and this argument is used as the length.out argument to the corresponding Variogram method. Defaults to 50.                                                                                                                                                                                                                                                                                                                                                                                                          |
| collapse   | an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if "fixed", the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles". |
| nint       | an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| robust     | an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| breaks     | an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in collapse is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| metric     | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                                                                                                            |
| ...        | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### Value

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, n.pairs, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If object includes a corSpatial element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute "modelVariog". The returned value inherits from class Variogram.

## Examples

```
Not run:
fm1 <- gls(weight ~ Time * Diet, BodyWeight)
Variogram(fm1, form = ~ Time | Rat)[1:10,]

End(Not run)
```

### Variogram.lme

*Calculate Semi-variogram for Residuals from an lme Object*

## Description

This method function calculates the semi-variogram for the within-group residuals from an `lme` fit. The semi-variogram values are calculated for pairs of residuals within the same group. If `collapse` is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (`robust = TRUE`) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

## Usage

```
S3 method for class 'lme'
Variogram(object, distance, form, resType, data,
 na.action, maxDist, length.out, collapse, nint, breaks,
 robust, metric, ...)
```

## Arguments

- |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>   | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>distance</code> | an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments <code>form</code> , <code>data</code> , and <code>metric</code> , unless <code>object</code> includes a <code>corSpatial</code> element, in which case the associated covariate (obtained with the <code>getCovariate</code> method) is used.                                          |
| <code>form</code>     | an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a <code> </code> operator in <code>form</code> ). Default is <code>~1</code> , implying that the observation order within the groups is used to obtain the distances.                                                                                                                                                           |
| <code>resType</code>  | an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson". |
| <code>data</code>     | an optional data frame in which to interpret the variables in <code>form</code> . By default, the same data used to fit <code>object</code> is used.                                                                                                                                                                                                                                                                                                                                                                                                           |

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| na.action  | a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes an error message to be printed and the function to terminate, if there are any incomplete observations.                                                                                                                                                                                                                                                                                                                                                                                                  |
| maxDist    | an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| length.out | an optional integer value. When <code>object</code> includes a <code>corSpatial</code> element, its semi-variogram values are calculated and this argument is used as the <code>length.out</code> argument to the corresponding <code>Variogram</code> method. Defaults to 50.                                                                                                                                                                                                                                                                                                                                                      |
| collapse   | an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if "fixed", the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles". |
| nint       | an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| robust     | an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| breaks     | an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in <code>collapse</code> is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| metric     | an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".                                                                                                                                                                                                                                            |
| ...        | some methods for this generic require additional arguments. None are used in this method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, `n.pairs`, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If `object` includes a `corSpatial` element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute "modelVariog". The returned value inherits from class `Variogram`.

Variogram(fm1, form = ~ Time | Rat, nint = 10, robust = TRUE)
```

varPower

*Power Variance Function***Description**

This function is a constructor for the `varPower` class, representing a power variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the power variance function is defined as  $\sigma^2(v) = |v|^{2\theta}$ , where  $\theta$  is the variance function coefficient. When a grouping factor is present, a different  $\theta$  is used for each factor level.

**Usage**

```
varPower(value, form, fixed)
```

**Arguments**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value</code> | an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in <code>form</code> . If value has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in <code>form</code> . If a grouping factor is present in <code>form</code> and <code>value</code> has length one, its value will be assigned to all grouping levels. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>form</code>  | an optional one-sided formula of the form $\sim v$ , or $\sim v \mid g$ , specifying a variance covariate <code>v</code> and, optionally, a grouping factor <code>g</code> for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using <code>"."</code> , representing a fitted model object from which fitted values ( <code>fitted(.)</code> ) and residuals ( <code>resid(.)</code> ) can be extracted (this allows the variance covariate to be updated during the optimization of an objective function). When a grouping factor is present in <code>form</code> , a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in $\sim v \mid g1 * g2 * g3$ . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to $\sim \text{fitted}(\cdot)$ representing a variance covariate given by the fitted values of a fitted model object and no grouping factor. |
| <code>fixed</code> | an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in <code>form</code> , <code>fixed</code> must have names identifying which coefficients are to be fixed. Coefficients included in <code>fixed</code> are not allowed to vary during the optimization of an objective function. Defaults to <code>NULL</code> , corresponding to no fixed coefficients.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Value**

a varPower object representing a power variance function structure, also inheriting from class varFunc.

vf1 <- varPower(0.2, form = ~age|Sex)
```

---

varWeights

*Extract Variance Function Weights*

---

**Description**

The inverse of the standard deviations corresponding to the variance function structure represented by object are returned.

**Usage**

```
varWeights(object)
```

**Arguments**

object           an object inheriting from class varFunc, representing a variance function structure.

**Value**

if object has a weights attribute, its value is returned; else NULL is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

## Examples

```
vf1 <- varPower(form=~age)
vf1 <- Initialize(vf1, Orthodont)
coef(vf1) <- 0.3
varWeights(vf1)[1:10]
```

`varWeights.glsStruct` *Variance Weights for glsStruct Object*

## Description

If object includes a `varStruct` component, the inverse of the standard deviations of the variance function structure represented by the corresponding `varFunc` object are returned; else, a vector of ones of length equal to the number of observations in the data frame used to fit the associated linear model is returned.

## Usage

```
S3 method for class 'glsStruct'
varWeights(object)
```

## Arguments

|                     |                                                                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code> | an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects. |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Value

if `object` includes a `varStruct` component, a vector with the corresponding variance weights; else, or a vector of ones.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

varWeights.lmeStruct    *Variance Weights for lmeStruct Object*

---

### Description

If object includes a varStruct component, the inverse of the standard deviations of the variance function structure represented by the corresponding varFunc object are returned; else, a vector of ones of length equal to the number of observations in the data frame used to fit the associated linear mixed-effects model is returned.

### Usage

```
S3 method for class 'lmeStruct'
varWeights(object)
```

### Arguments

**object**                an object inheriting from class `lmeStruct`, representing a list of linear mixed-effects model components, such as `reStruct`, `corStruct`, and `varFunc` objects.

### Value

if object includes a varStruct component, a vector with the corresponding variance weights; else, or a vector of ones.

---

**[.pdMat***Subscript a pdMat Object*

---

**Description**

This method function extracts sub-matrices from the positive-definite matrix represented by *x*.

**Usage**

```
S3 method for class 'pdMat'
x[i, j, drop = TRUE]
S3 replacement method for class 'pdMat'
x[i, j] <- value
```

**Arguments**

|              |                                                                                                                                                                                                           |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>x</i>     | an object inheriting from class <i>pdMat</i> representing a positive-definite matrix.                                                                                                                     |
| <i>i, j</i>  | optional subscripts applying respectively to the rows and columns of the positive-definite matrix represented by <i>object</i> . When <i>i</i> ( <i>j</i> ) is omitted, all rows (columns) are extracted. |
| <i>drop</i>  | a logical value. If TRUE, single rows or columns are converted to vectors. If FALSE the returned value retains its matrix representation.                                                                 |
| <i>value</i> | a vector, or matrix, with the replacement values for the relevant piece of the matrix represented by <i>x</i> .                                                                                           |

**Value**

if *i* and *j* are identical, the returned value will be *pdMat* object with the same class as *x*. Otherwise, the returned value will be a matrix. In the case a single row (or column) is selected, the returned value may be converted to a vector, according to the rules above.

## The nnet package

---

class.ind

*Generates Class Indicator Matrix from a Factor*

---

### Description

Generates a class indicator function from a given factor.

### Usage

class.ind(c1)

### Arguments

c1 factor or vector of classes for cases.

### Value

a matrix which is zero except for the column corresponding to the class.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

### Examples

```
The function is currently defined as
class.ind <- function(c1)
{
 n <- length(c1)
 cl <- as.factor(c1)
 x <- matrix(0, n, length(levels(cl)))
 x[(1:n) + n*(unclass(cl)-1)] <- 1
 dimnames(x) <- list(names(cl), levels(cl))
 x
}
```

---

**multinom***Fit Multinomial Log-linear Models*

---

## Description

Fits multinomial log-linear models via neural networks.

## Usage

```
multinom(formula, data, weights, subset, na.action,
 contrasts = NULL, Hess = FALSE, summ = 0, censored = FALSE,
 model = FALSE, ...)
```

## Arguments

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>formula</b>   | a formula expression as for regression models, of the form <code>response ~ predictors</code> . The response should be a factor or a matrix with K columns, which will be interpreted as counts for each of K classes. A log-linear model is fitted, with coefficients zero for the first class. An offset can be included: it should be a numeric matrix with K columns if the response is either a matrix with K columns or a factor with $K > 2$ classes, or a numeric vector for a response factor with 2 levels. See the documentation of <code>formula()</code> for other details. |
| <b>data</b>      | an optional data frame in which to interpret the variables occurring in <code>formula</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>weights</b>   | optional case weights in fitting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>subset</b>    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>na.action</b> | a function to filter missing data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>contrasts</b> | a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Hess</b>      | logical for whether the Hessian (the observed/expected information matrix) should be returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>summ</b>      | integer; if non-zero summarize by deleting duplicate rows and adjust weights. Methods 1 and 2 differ in speed (2 uses C); method 3 also combines rows with the same X and different Y, which changes the baseline for the deviance.                                                                                                                                                                                                                                                                                                                                                      |
| <b>censored</b>  | If Y is a matrix with $K > 2$ columns, interpret the entries as one for possible classes, zero for impossible classes, rather than as counts.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>model</b>     | logical. If true, the model frame is saved as component <code>model</code> of the returned object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>...</b>       | additional arguments for <code>nnet</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Details

`multinom` calls `nnet`. The variables on the rhs of the formula should be roughly scaled to [0,1] or the fit will be slow or may not converge at all.

### Value

A nnet object with additional components:

|          |                                                                                                                                                |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------|
| deviance | the residual deviance, compared to the full saturated model (that explains individual observations exactly). Also, minus twice log-likelihood. |
| edf      | the (effective) number of degrees of freedom used by the model                                                                                 |
| AIC      | the AIC for this fit.                                                                                                                          |
| Hessian  | (if Hess is true).                                                                                                                             |
| model    | (if model is true).                                                                                                                            |

### Description

Fit single-hidden-layer neural network, possibly with skip-layer connections.

**Usage**

```
nnet(x, ...)

S3 method for class 'formula'
nnet(formula, data, weights, ...,
 subset, na.action, contrasts = NULL)

Default S3 method:
nnet(x, y, weights, size, Wts, mask,
 linout = FALSE, entropy = FALSE, softmax = FALSE,
 censored = FALSE, skip = FALSE, rang = 0.7, decay = 0,
 maxit = 100, Hess = FALSE, trace = TRUE, MaxNWts = 1000,
 abstol = 1.0e-4, reltol = 1.0e-8, ...)
```

**Arguments**

|                  |                                                                                                                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>formula</b>   | A formula of the form <code>class ~ x1 + x2 + ...</code>                                                                                                                                                                                                                                 |
| <b>x</b>         | matrix or data frame of <code>x</code> values for examples.                                                                                                                                                                                                                              |
| <b>y</b>         | matrix or data frame of target values for examples.                                                                                                                                                                                                                                      |
| <b>weights</b>   | (case) weights for each example – if missing defaults to 1.                                                                                                                                                                                                                              |
| <b>size</b>      | number of units in the hidden layer. Can be zero if there are skip-layer units.                                                                                                                                                                                                          |
| <b>data</b>      | Data frame from which variables specified in <code>formula</code> are preferentially to be taken.                                                                                                                                                                                        |
| <b>subset</b>    | An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)                                                                                                                                                                   |
| <b>na.action</b> | A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)  |
| <b>contrasts</b> | a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.                                                                                                                                                                               |
| <b>Wts</b>       | initial parameter vector. If missing chosen at random.                                                                                                                                                                                                                                   |
| <b>mask</b>      | logical vector indicating which parameters should be optimized (default all).                                                                                                                                                                                                            |
| <b>linout</b>    | switch for linear output units. Default logistic output units.                                                                                                                                                                                                                           |
| <b>entropy</b>   | switch for entropy (= maximum conditional likelihood) fitting. Default by least-squares.                                                                                                                                                                                                 |
| <b>softmax</b>   | switch for softmax (log-linear model) and maximum conditional likelihood fitting. <code>linout</code> , <code>entropy</code> , <code>softmax</code> and <code>censored</code> are mutually exclusive.                                                                                    |
| <b>censored</b>  | A variant on <code>softmax</code> , in which non-zero targets mean possible classes. Thus for <code>softmax</code> a row of <code>(0, 1, 1)</code> means one example each of classes 2 and 3, but for <code>censored</code> it means one example whose class is only known to be 2 or 3. |
| <b>skip</b>      | switch to add skip-layer connections from input to output.                                                                                                                                                                                                                               |
| <b>rang</b>      | Initial random weights on $[-\text{rang}, \text{rang}]$ . Value about 0.5 unless the inputs are large, in which case it should be chosen so that <code>rang * max( x )</code> is about 1.                                                                                                |
| <b>decay</b>     | parameter for weight decay. Default 0.                                                                                                                                                                                                                                                   |
| <b>maxit</b>     | maximum number of iterations. Default 100.                                                                                                                                                                                                                                               |

|         |                                                                                                                                                                                       |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hess    | If true, the Hessian of the measure of fit at the best set of weights found is returned as component <code>Hessian</code> .                                                           |
| trace   | switch for tracing optimization. Default TRUE.                                                                                                                                        |
| MaxNWts | The maximum allowable number of weights. There is no intrinsic limit in the code, but increasing <code>MaxNWts</code> will probably allow fits that are very slow and time-consuming. |
| abstol  | Stop if the fit criterion falls below <code>abstol</code> , indicating an essentially perfect fit.                                                                                    |
| reltol  | Stop if the optimizer is unable to reduce the fit criterion by a factor of at least $1 - \text{reltol}$ .                                                                             |
| ...     | arguments passed to or from other methods.                                                                                                                                            |

## Details

If the response in `formula` is a factor, an appropriate classification network is constructed; this has one output and entropy fit if the number of levels is two, and a number of outputs equal to the number of classes and a softmax output stage for more levels. If the response is not a factor, it is passed on unchanged to `nnet.default`.

Optimization is done via the BFGS method of [optim](#).

## Value

object of class "nnet" or "nnet.formula". Mostly internal structure, but has components

|               |                                                                 |
|---------------|-----------------------------------------------------------------|
| wts           | the best set of weights found                                   |
| value         | value of fitting criterion plus weight decay term.              |
| fitted.values | the fitted values for the training data.                        |
| residuals     | the residuals for the training data.                            |
| convergence   | 1 if the maximum number of iterations was reached, otherwise 0. |

## Examples

```
use half the iris data
ir <- rbind(iris3[,1],iris3[,2],iris3[,3])
targets <- class.ind(c(rep("s", 50), rep("c", 50), rep("v", 50)))
samp <- c(sample(1:50,25), sample(51:100,25), sample(101:150,25))
ir1 <- nnet(ir[samp,], targets[samp,], size = 2, rang = 0.1,
 decay = 5e-4, maxit = 200)
test.cl <- function(true, pred) {
 true <- max.col(true)
 cres <- max.col(pred)
 table(true, cres)
}
```

```

test.cl(targets[-samp,], predict(ir1, ir[-samp,]))

or
ird <- data.frame(rbind(iris3[,1], iris3[,2], iris3[,3]),
 species = factor(c(rep("s",50), rep("c", 50), rep("v", 50))))
ir.nn2 <- nnet(species ~ ., data = ird, subset = samp, size = 2, rang = 0.1,
 decay = 5e-4, maxit = 200)
table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))

```

**nnetHess***Evaluates Hessian for a Neural Network***Description**

Evaluates the Hessian (matrix of second derivatives) of the specified neural network. Normally called via argument Hess=TRUE to nnet or via vcov.multinom.

**Usage**

```
nnetHess(net, x, y, weights)
```

**Arguments**

- |         |                                           |
|---------|-------------------------------------------|
| net     | object of class nnet as returned by nnet. |
| x       | training data.                            |
| y       | classes for training data.                |
| weights | the (case) weights used in the nnet fit.  |

**Value**

square symmetric matrix of the Hessian evaluated at the weights stored in the net.

**Examples**

```

use half the iris data
ir <- rbind(iris3[,1], iris3[,2], iris3[,3])
targets <- matrix(c(rep(c(1,0,0),50), rep(c(0,1,0),50), rep(c(0,0,1),50),
150, 3, byrow=TRUE)
samp <- c(sample(1:50,25), sample(51:100,25), sample(101:150,25))
ir1 <- nnet(ir[samp,], targets[samp,], size=2, rang=0.1, decay=5e-4, maxit=200)
eigen(nnetHess(ir1, ir[samp,], targets[samp,]), TRUE)$values

```

---

**predict.nnet***Predict New Examples by a Trained Neural Net*

---

**Description**

Predict new examples by a trained neural net.

**Usage**

```
S3 method for class 'nnet'
predict(object, newdata, type = c("raw", "class"), ...)
```

**Arguments**

|         |                                                                                                            |
|---------|------------------------------------------------------------------------------------------------------------|
| object  | an object of class <code>nnet</code> as returned by <code>nnet</code> .                                    |
| newdata | matrix or data frame of test examples. A vector is considered to be a row vector comprising a single case. |
| type    | Type of output                                                                                             |
| ...     | arguments passed to or from other methods.                                                                 |

**Details**

This function is a method for the generic function `predict()` for class "`nnet`". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.nnet(x)` regardless of the class of the object.

**Value**

If `type = "raw"`, the matrix of values returned by the trained network; if `type = "class"`, the corresponding class (which is probably only useful if the net was generated by `nnet.formula`).

**References**

- Ripley, B. D. (1996) *Pattern Recognition and Neural Networks*. Cambridge.  
Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))

```

---

**which.is.max** *Find Maximum Position in Vector*

---

## Description

Find the maximum position in a vector, breaking ties at random.

## Usage

`which.is.max(x)`

## Arguments

`x` a vector

## Details

Ties are broken at random.

## Value

index of a maximal value.

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

## See Also

`max.col`, `which.max` which takes the first of ties.

## Examples

```

Not run:
pred <- predict(nnet, test)
table(true, apply(pred,1,which.is.max))

End(Not run)

```

## The rpart package

---

car.test.frame

*Automobile Data from 'Consumer Reports' 1990*

---

### Description

The car.test.frame data frame has 60 rows and 8 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*. This is part of a larger dataset, some columns of which are given in [cu.summary](#).

### Usage

`car.test.frame`

### Format

This data frame contains the following columns:

`Price` a numeric vector giving the list price in US dollars of a standard model

`Country` of origin, a factor with levels ‘France’, ‘Germany’, ‘Japan’ , ‘Japan/USA’, ‘Korea’, ‘Mexico’, ‘Sweden’ and ‘USA’

`Reliability` a numeric vector coded 1 to 5.

`Mileage` fuel consumption miles per US gallon, as tested.

`Type` a factor with levels Compact Large Medium Small Sporty Van

`Weight` kerb weight in pounds.

`Disp.` the engine capacity (displacement) in litres.

`HP` the net horsepower of the vehicle.

### Source

*Consumer Reports*, April, 1990, pp. 235–288 quoted in

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA, pp. 46–47.

**See Also**

[car90, cu.summary](#)

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)
```

car90

*Automobile Data from 'Consumer Reports' 1990*

**Description**

Data on 111 cars, taken from pages 235–255, 281–285 and 287–288 of the April 1990 *Consumer Reports* Magazine.

**Usage**

```
data(car90)
```

**Format**

The data frame contains the following columns

**Country** a factor giving the country in which the car was manufactured

**Disp** engine displacement in cubic inches

**Disp2** engine displacement in liters

**Eng.Rev** engine revolutions per mile, or engine speed at 60 mph

**Front.Hd** distance between the car's head-liner and the head of a 5 ft. 9 in. front seat passenger, in inches, as measured by CU

**Frt.Leg.Room** maximum front leg room, in inches, as measured by CU

**Frt.Shld** front shoulder room, in inches, as measured by CU

**Gear.Ratio** the overall gear ratio, high gear, for manual transmission

**Gear2** the overall gear ratio, high gear, for automatic transmission

**HP** net horsepower

**HP.revs** the red line—the maximum safe engine speed in rpm

**Height** height of car, in inches, as supplied by manufacturer

**Length** overall length, in inches, as supplied by manufacturer

**Luggage** luggage space

**Mileage** a numeric vector of gas mileage in miles/gallon as tested by CU; contains NAs.

**Model2** alternate name, if the car was sold under two labels

**Price** list price with standard equipment, in dollars

**Rear.Hd** distance between the car's head-liner and the head of a 5 ft 9 in. rear seat passenger, in inches, as measured by CU

**Rear.Seating** rear fore-and-aft seating room, in inches, as measured by CU

**RearShld** rear shoulder room, in inches, as measured by CU

**Reliability** an ordered factor with levels ‘Much worse’ < ‘worse’ < ‘average’ < ‘better’ < ‘Much better’: contains NAs.

**Rim** factor giving the rim size

**Sratio.m** Number of turns of the steering wheel required for a turn of 30 foot radius, manual steering

**Sratio.p** Number of turns of the steering wheel required for a turn of 30 foot radius, power steering

**Steering** steering type offered: manual, power, or both

**Tank** fuel refill capacity in gallons

**Tires** factor giving tire size

**Trans1** manual transmission, a factor with levels ‘’, ‘man.4’, ‘man.5’ and ‘man.6’

**Trans2** automatic transmission, a factor with levels ‘’, ‘auto.3’, ‘auto.4’, and ‘auto.CVT’. No car is missing both the manual and automatic transmission variables, but several had both as options

**Turning** the radius of the turning circle in feet

**Type** a factor giving the general type of car. The levels are: ‘Small’, ‘Sporty’, ‘Compact’, ‘Medium’, ‘Large’, ‘Van’

**Weight** an order statistic giving the relative weights of the cars; 1 is the lightest and 111 is the heaviest

**Wheel.base** length of wheelbase, in inches, as supplied by manufacturer

**Width** width of car, in inches, as supplied by manufacturer

## Source

This is derived (with permission) from the data set `car.all` in S-PLUS, but with some further clean up of variable names and definitions.

## See Also

[car.test.frame](#), [cu.summary](#) for extracts from other versions of the dataset.

## Examples

```
data(car90)
plot(car90$Price/1000, car90$Weight,
 xlab = "Price (thousands)", ylab = "Weight (lbs)")
mlowess <- function(x, y, ...) {
 keep <- !(is.na(x) | is.na(y))
 lowess(x[keep], y[keep], ...)
}
with(car90, lines(mlowess(Price/1000, Weight, f = 0.5)))
```

---

**cu.summary**

*Automobile Data from 'Consumer Reports' 1990*

---

## Description

The **cu.summary** data frame has 117 rows and 5 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*.

## Usage

**cu.summary**

## Format

This data frame contains the following columns:

**Price** a numeric vector giving the list price in US dollars of a standard model

**Country** of origin, a factor with levels ‘Brazil’, ‘England’, ‘France’, ‘Germany’, ‘Japan’, ‘Japan/USA’, ‘Korea’, ‘Mexico’, ‘Sweden’ and ‘USA’

**Reliability** an ordered factor with levels ‘Much worse’ < ‘worse’ < ‘average’ < ‘better’ < ‘Much better’

**Mileage** fuel consumption miles per US gallon, as tested.

**Type** a factor with levels Compact Large Medium Small Sporty Van

---

kyphosis

*Data on Children who have had Corrective Spinal Surgery*

---

### Description

The `kyphosis` data frame has 81 rows and 4 columns, representing data on children who have had corrective spinal surgery

### Usage

`kyphosis`

### Format

This data frame contains the following columns:

`Kyphosis` a factor with levels `absent` `present` indicating if a kyphosis (a type of deformation) was present after the operation.  
`Age` in months  
`Number` the number of vertebrae involved  
`Start` the number of the first (topmost) vertebra operated on.

### Source

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA.

### Examples

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
 parms = list(prior = c(0.65, 0.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis,
 control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = TRUE)
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
```

---

`labels.rpart`

*Create Split Labels For an rpart Object*

---

### Description

This function provides labels for the branches of an `rpart` tree.

### Usage

```
S3 method for class 'rpart'
labels(object, digits = 4, minlength = 1L, pretty, collapse = TRUE, ...)
```

### Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.                                                                                                                                                                                                                                                                           |
| <code>digits</code>    | the number of digits to be used for numeric values. All of the <code>rpart</code> functions that call labels explicitly set this value, with <code>options("digits")</code> as the default.                                                                                                                                                                                                                                                                                   |
| <code>minlength</code> | the minimum length for abbreviation of character or factor variables. If 0 no abbreviation is done; if 1 single English letters are used, first lower case than upper case (with a maximum of 52 levels). If the value is greater than , the <code>abbreviate</code> function is used, passed the <code>minlength</code> argument.                                                                                                                                            |
| <code>pretty</code>    | an argument included for compatibility with the <code>tree</code> package: <code>pretty = 0</code> implies <code>minlength = 0L</code> , <code>pretty = NULL</code> implies <code>minlength = 1L</code> , and <code>pretty = TRUE</code> implies <code>minlength = 4L</code> .                                                                                                                                                                                                |
| <code>collapse</code>  | logical. The returned set of labels is always of the same length as the number of nodes in the tree.<br>If <code>collapse = TRUE</code> (default), the returned value is a vector of labels for the branch leading into each node, with "root" as the label for the top node.<br>If <code>FALSE</code> , the returned value is a two column matrix of labels for the left and right branches leading out from each node, with "leaf" as the branch labels for terminal nodes. |
| <code>...</code>       | optional arguments to <code>abbreviate</code> .                                                                                                                                                                                                                                                                                                                                                                                                                               |

### Value

Vector of split labels (`collapse = TRUE`) or matrix of left and right splits (`collapse = FALSE`) for the supplied `rpart` object. This function is called by printing methods for `rpart` and is not intended to be called directly by the users.

### See Also

[abbreviate](#)

`meanvar.rpart`

*Mean-Variance Plot for an Rpart Object*

### Description

Creates a plot on the current graphics device of the deviance of the node divided by the number of observations at the node. Also returns the node number.

### Usage

```
meanvar(tree, ...)

S3 method for class 'rpart'
meanvar(tree, xlab = "ave(y)", ylab = "ave(deviance)", ...)
```

**Arguments**

- tree** fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.
- xlab** x-axis label for the plot.
- ylab** y-axis label for the plot.
- ...** additional graphical parameters may be supplied as arguments to this function.

**Value**

an invisible list containing the following vectors is returned.

- x** fitted value at terminal nodes (`yval`).
- y** deviance of node divided by number of observations at node.
- label** node number.

**Side Effects**

a plot is put on the current graphics device.

**See Also**

[plot.rpart](#).

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
meanvar(z.auto, log = 'xy')
```

**na.rpart**

*Handles Missing Values in an Rpart Object*

**Description**

Handles missing values in an "rpart" object.

**Usage**

```
na.rpart(x)
```

**Arguments**

- x** a model frame.

**Details**

Default function that handles missing values when calling the function `rpart`.

It omits cases where part of the response is missing or all the explanatory variables are missing.

---

**path.rpart***Follow Paths to Selected Nodes of an Rpart Object*

---

## Description

Returns a names list where each element contains the splits on the path from the root to the selected nodes.

## Usage

```
path.rpart(tree, nodes, pretty = 0, print.it = TRUE)
```

## Arguments

|                       |                                                                                                                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tree</code>     | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.                                     |
| <code>nodes</code>    | an integer vector containing indices (node numbers) of all nodes for which paths are desired. If missing, user selects nodes as described below.                                                                                        |
| <code>pretty</code>   | an integer denoting the extent to which factor levels in split labels will be abbreviated. A value of (0) signifies no abbreviation. A NULL, the default, signifies using elements of letters to represent the different factor levels. |
| <code>print.it</code> | Logical. Denotes whether paths will be printed out as nodes are interactively selected. Irrelevant if <code>nodes</code> argument is supplied.                                                                                          |

## Details

The function has a required argument as an `rpart` object and a list of nodes as optional arguments. Omitting a list of nodes will cause the function to wait for the user to select nodes from the dendrogram. It will return a list, with one component for each node specified or selected. The component contains the sequence of splits leading to that node. In the graphical interaction, the individual paths are printed out as nodes are selected.

## Value

A named (by node) list, each element of which contains all the splits on the path from the root to the specified or selected nodes.

## Graphical Interaction

A dendrogram of the `rpart` object is expected to be visible on the graphics device, and a graphics input device (e.g. a mouse) is required. Clicking (the selection button) on a node selects that node. This process may be repeated any number of times. Clicking the exit button will stop the selection process and return the list of paths.

## References

This function was modified from `path.tree` in S.

## Examples

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
print(fit)
path.rpart(fit, node = c(11, 22))
```

**plot.rpart**

*Plot an Rpart Object*

## Description

Plots an rpart object on the current graphics device.

## Usage

```
S3 method for class 'rpart'
plot(x, uniform = FALSE, branch = 1, compress = FALSE, nspace,
 margin = 0, minbranch = 0.3, ...)
```

## Arguments

- |                  |                                                                                                                                                                                                                                                                                                                                                         |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>         | a fitted object of class "rpart", containing a classification, regression, or rate tree.                                                                                                                                                                                                                                                                |
| <b>uniform</b>   | if TRUE, uniform vertical spacing of the nodes is used; this may be less cluttered when fitting a large plot onto a page. The default is to use a non-uniform spacing proportional to the error in the fit.                                                                                                                                             |
| <b>branch</b>    | controls the shape of the branches from parent to child node. Any number from 0 to 1 is allowed. A value of 1 gives square shouldered branches, a value of 0 give V shaped branches, with other values being intermediate.                                                                                                                              |
| <b>compress</b>  | if FALSE, the leaf nodes will be at the horizontal plot coordinates of 1:nleaves. If TRUE, the routine attempts a more compact arrangement of the tree. The compaction algorithm assumes uniform=TRUE; surprisingly, the result is usually an improvement even when that is not the case.                                                               |
| <b>nspace</b>    | the amount of extra space between a node with children and a leaf, as compared to the minimal space between leaves. Applies to compressed trees only. The default is the value of branch.                                                                                                                                                               |
| <b>margin</b>    | an extra fraction of white space to leave around the borders of the tree. (Long labels sometimes get cut off by the default computation).                                                                                                                                                                                                               |
| <b>minbranch</b> | set the minimum length for a branch to minbranch times the average branch length. This parameter is ignored if uniform=TRUE. Sometimes a split will give very little improvement, or even (in the classification case) no improvement at all. A tree with branch lengths strictly proportional to improvement leaves no room to squeeze in node labels. |
| <b>...</b>       | arguments to be passed to or from other methods.                                                                                                                                                                                                                                                                                                        |

## Details

This function is a method for the generic function `plot`, for objects of class `rpart`. The y-coordinate of the top node of the tree will always be 1.

**Value**

The coordinates of the nodes are returned as a list, with components `x` and `y`.

**Side Effects**

An unlabeled plot is produced on the current graphics device.

In order to build up a plot in the usual S style, e.g., a separate `text` command for adding labels, some extra information about the plot needs be retained. This is kept in `options("rpartplot")`; there is no need for this option to be retained from one R session to another, however.

**See Also**

[rpart](#), [text.rpart](#)

**Examples**

```
fit <- rpart(Price ~ Mileage + Type + Country, cu.summary)
par(xpd = TRUE)
plot(fit, compress = TRUE)
text(fit, use.n = TRUE)
```

**plotcp**

*Plot a Complexity Parameter Table for an Rpart Fit*

**Description**

Gives a visual representation of the cross-validation results in an `rpart` object.

**Usage**

```
plotcp(x, minline = TRUE, lty = 3, col = 1,
 upper = c("size", "splits", "none"), ...)
```

**Arguments**

|                      |                                                                                                                |
|----------------------|----------------------------------------------------------------------------------------------------------------|
| <code>x</code>       | an object of class " <code>rpart</code> "                                                                      |
| <code>minline</code> | whether a horizontal line is drawn 1SE above the minimum of the curve.                                         |
| <code>lty</code>     | line type for this line                                                                                        |
| <code>col</code>     | colour for this line                                                                                           |
| <code>upper</code>   | what is plotted on the top axis: the size of the tree (the number of leaves), the number of splits or nothing. |
| <code>...</code>     | additional plotting parameters                                                                                 |

**Details**

The set of possible cost-complexity prunings of a tree from a nested set. For the geometric means of the intervals of values of `cp` for which a pruning is optimal, a cross-validation has (usually) been done in the initial construction by [rpart](#). The `cptable` in the fit contains the mean and standard deviation of the errors in the cross-validated prediction against each of the geometric means, and these are plotted by this function. A good choice of `cp` for pruning is often the leftmost value for which the mean lies below the horizontal line.

**Value**

None.

**Side Effects**

A plot is produced on the current graphical device.

**See Also**

[rpart](#), [printcp](#), [rpart.object](#)

**post.rpart**

*PostScript Presentation Plot of an Rpart Object*

**Description**

Generates a PostScript presentation plot of an `rpart` object.

**Usage**

```
post(tree, ...)

S3 method for class 'rpart'
post(tree, title.,
 filename = paste(deparse(substitute(tree)), ".ps", sep = ""),
 digits = getOption("digits") - 2, pretty = TRUE,
 use.n = TRUE, horizontal = TRUE, ...)
```

**Arguments**

|                         |                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tree</code>       | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.                                                                                                                   |
| <code>title.</code>     | a title which appears at the top of the plot. By default, the name of the <code>rpart</code> endpoint is printed out.                                                                                                                                                                                                 |
| <code>filename</code>   | ASCII file to contain the output. By default, the name of the file is the name of the object given by <code>rpart</code> (with the suffix .ps added). If <code>filename = ""</code> , the plot appears on the current graphical device.                                                                               |
| <code>digits</code>     | number of significant digits to include in numerical data.                                                                                                                                                                                                                                                            |
| <code>pretty</code>     | an integer denoting the extent to which factor levels will be abbreviated in the character strings defining the splits; (0) signifies no abbreviation of levels. A NULL signifies using elements of letters to represent the different factor levels. The default (TRUE) indicates the maximum possible abbreviation. |
| <code>use.n</code>      | Logical. If TRUE (default), adds to label (#events level1/ #events level2/etc. for method <code>class</code> , <code>n</code> for method <code>anova</code> , and #events/n for methods <code>poisson</code> and <code>exp</code> ).                                                                                  |
| <code>horizontal</code> | Logical. If TRUE (default), plot is horizontal. If FALSE, plot appears as landscape.                                                                                                                                                                                                                                  |
| <code>...</code>        | other arguments to the <code>postscript</code> function.                                                                                                                                                                                                                                                              |

## Details

The plot created uses the functions `plot.rpart` and `text.rpart` (with the `fancy` option). The settings were chosen because they looked good to us, but other options may be better, depending on the `rpart` object. Users are encouraged to write their own function containing favorite options.

## Side Effects

a plot of `rpart` is created using the `postscript` driver, or the current device if `filename = ""`.

## See Also

[plot.rpart](#), [rpart](#), [text.rpart](#), [abbreviate](#)

## Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
post(z.auto, file = "") # display tree on active device
now construct postscript version on file "pretty.ps"
with no title
post(z.auto, file = "pretty.ps", title = " ")
z.hp <- rpart(Mileage ~ Weight + HP, car.test.frame)
post(z.hp)
```

**predict.rpart**

*Predictions from a Fitted Rpart Object*

## Description

Returns a vector of predicted responses from a fitted `rpart` object.

## Usage

```
S3 method for class 'rpart'
predict(object, newdata,
 type = c("vector", "prob", "class", "matrix"),
 na.action = na.pass, ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | fitted model object of class " <code>rpart</code> ". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.                                                                                                                                                          |
| <code>newdata</code>   | data frame containing the values at which predictions are required. The predictors referred to in the right side of <code>formula(object)</code> must be present by name in <code>newdata</code> . If missing, the fitted values are returned.                                                                                                                              |
| <code>type</code>      | character string denoting the type of predicted value returned. If the <code>rpart</code> object is a classification tree, then the default is to return <code>prob</code> predictions, a matrix whose columns are the probability of the first, second, etc. class. (This agrees with the default behavior of <code>tree</code> ). Otherwise, a vector result is returned. |
| <code>na.action</code> | a function to determine what should be done with missing values in <code>newdata</code> . The default is to pass them down the tree using surrogates in the way selected when the model was built. Other possibilities are <code>na.omit</code> and <code>na.fail</code> .                                                                                                  |
| ...                    | further arguments passed to or from other methods.                                                                                                                                                                                                                                                                                                                          |

## Details

This function is a method for the generic function predict for class "rpart". It can be invoked by calling predict for an object of the appropriate class, or directly by calling predict.rpart regardless of the class of the object.

## Value

A new object is obtained by dropping newdata down the object. For factor predictors, if an observation contains a level not used to grow the tree, it is left at the deepest possible node and frame\$yval at the node is the prediction.

If type = "vector":

vector of predicted responses. For regression trees this is the mean response at the node, for Poisson trees it is the estimated response rate, and for classification trees it is the predicted class (as a number).

If type = "prob":

(for a classification tree) a matrix of class probabilities.

If type = "matrix":

a matrix of the full responses (frame\$yval2 if this exists, otherwise frame\$yval). For regression trees, this is the mean response, for Poisson trees it is the response rate and the number of events at that node in the fitted tree, and for classification trees it is the concatenation of the predicted class, the class counts at that node in the fitted tree, and the class probabilities.

If type = "class":

(for a classification tree) a factor of classifications based on the responses.

## Examples

```

z.auto <- rpart(Mileage ~ Weight, car.test.frame)
predict(z.auto)

fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
predict(fit, type = "prob") # class probabilities (default)
predict(fit, type = "vector") # level numbers
predict(fit, type = "class") # factor
predict(fit, type = "matrix") # level number, class frequencies, probabilities

sub <- c(sample(1:50, 25), sample(51:100, 25), sample(101:150, 25))
fit <- rpart(Species ~ ., data = iris, subset = sub)
fit
table(predict(fit, iris[-sub,], type = "class"), iris[-sub, "Species"])

```

## Description

This function prints an rpart object. It is a method for the generic function print of class "rpart".

## Usage

```
S3 method for class 'rpart'
print(x, minlength = 0, spaces = 2, cp, digits = getOption("digits"), ...)
```

## Arguments

|           |                                                                                                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x         | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function. |
| minlength | Controls the abbreviation of labels: see <a href="#">labels.rpart</a> .                                                                                                                             |
| spaces    | the number of spaces to indent nodes of increasing depth.                                                                                                                                           |
| digits    | the number of digits of numbers to print.                                                                                                                                                           |
| cp        | prune all nodes with a complexity less than cp from the printout. Ignored if unspecified.                                                                                                           |
| ...       | arguments to be passed to or from other methods.                                                                                                                                                    |

## Details

This function is a method for the generic function `print` for class "rpart". It can be invoked by calling `print` for an object of the appropriate class, or directly by calling `print.rpart` regardless of the class of the object.

## Side Effects

A semi-graphical layout of the contents of `x$frame` is printed. Indentation is used to convey the tree topology. Information for each node includes the node number, split, size, deviance, and fitted value. For the "class" method, the class probabilities are also printed.

## Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
z.auto
Not run: node), split, n, deviance, yval
 * denotes terminal node

 1) root 60 1354.58300 24.58333
 2) Weight>=2567.5 45 361.20000 22.46667
 4) Weight>=3087.5 22 61.31818 20.40909 *
 5) Weight<3087.5 23 117.65220 24.43478
 10) Weight>=2747.5 15 60.40000 23.80000 *
 11) Weight<2747.5 8 39.87500 25.62500 *
 3) Weight<2567.5 15 186.93330 30.93333 *

End(Not run)
```

---

printcp                  *Displays CP table for Fitted Rpart Object*

---

## Description

Displays the cp table for fitted rpart object.

## Usage

```
printcp(x, digits =getOption("digits") - 2)
```

## Arguments

- x                        fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
- digits                  the number of digits of numbers to print.

## Details

Prints a table of optimal prunings based on a complexity parameter.

**prune.rpart***Cost-complexity Pruning of an Rpart Object***Description**

Determines a nested sequence of subtrees of the supplied `rpart` object by recursively snipping off the least important splits, based on the complexity parameter (`cp`).

**Usage**

```
prune(tree, ...)

S3 method for class 'rpart'
prune(tree, cp, ...)
```

**Arguments**

|                   |                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tree</code> | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function. |
| <code>cp</code>   | Complexity parameter to which the <code>rpart</code> object will be trimmed.                                                                                                                        |
| <code>...</code>  | further arguments passed to or from other methods.                                                                                                                                                  |

**Value**

A new `rpart` object that is trimmed to the value `cp`.

**See Also**

[rpart](#)

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
zp <- prune(z.auto, cp = 0.1)
plot(zp) #plot smaller rpart object
```

**residuals.rpart***Residuals From a Fitted Rpart Object***Description**

Method for `residuals` for an `rpart` object.

**Usage**

```
S3 method for class 'rpart'
residuals(object, type = c("usual", "pearson", "deviance"), ...)
```

**Arguments**

- object fitted model object of class "rpart".
- type Indicates the type of residual desired.
- For regression or anova trees all three residual definitions reduce to  $y - \text{fitted}$ . This is the residual returned for user method trees as well.
- For classification trees the usual residuals are the misclassification losses  $L(\text{actual}, \text{predicted})$  where  $L$  is the loss matrix. With default losses this residual is 0/1 for correct/incorrect classification. The pearson residual is  $(1 - \text{fitted})/\sqrt{\text{fitted}(1 - \text{fitted})}$  and the deviance residual is  $\sqrt{-2 \log L}$ .
- For poisson and exp (or survival) trees, the usual residual is the observed - expected number of events. The pearson and deviance residuals are as defined in McCullagh and Nelder.
- ... further arguments passed to or from other methods.

**Value**

Vector of residuals of type type from a fitted rpart object.

**References**

McCullagh P. and Nelder, J. A. (1989) *Generalized Linear Models*. London: Chapman and Hall.

**Examples**

```
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
 data = solder, method = "anova")
summary(residuals(fit))
plot(predict(fit),residuals(fit))
```

**Description**

Fit a rpart model

**Usage**

```
rpart(formula, data, weights, subset, na.action = na.rpart, method,
 model = FALSE, x = FALSE, y = TRUE, parms, control, cost, ...)
```

**Arguments**

- formula a [formula](#), with a response but no interaction terms. If this is a data frame, that is taken as the model frame (see [model.frame](#)).
- data an optional data frame in which to interpret the variables named in the formula.
- weights optional case weights.
- subset optional expression saying that only a subset of the rows of the data should be used in the fit.

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| na.action | the default action deletes all observations for which y is missing, but keeps those in which one or more predictors are missing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| method    | one of "anova", "poisson", "class" or "exp". If method is missing then the routine tries to make an intelligent guess. If y is a survival object, then method = "exp" is assumed, if y has 2 columns then method = "poisson" is assumed, if y is a factor then method = "class" is assumed, otherwise method = "anova" is assumed. It is wisest to specify the method directly, especially as more criteria may added to the function in future.<br>Alternatively, method can be a list of functions named init, split and eval. Examples are given in the file 'tests/usersplits.R' in the sources, and in the vignettes 'User Written Split Functions'.                                                                                                                                |
| model     | if logical: keep a copy of the model frame in the result? If the input value for model is a model frame (likely from an earlier call to the rpart function), then this frame is used rather than constructing new data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| x         | keep a copy of the x matrix in the result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| y         | keep a copy of the dependent variable in the result. If missing and model is supplied this defaults to FALSE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| parms     | optional parameters for the splitting function.<br>Anova splitting has no parameters.<br>Poisson splitting has a single parameter, the coefficient of variation of the prior distribution on the rates. The default value is 1.<br>Exponential splitting has the same parameter as Poisson.<br>For classification splitting, the list can contain any of: the vector of prior probabilities (component prior), the loss matrix (component loss) or the splitting index (component split). The priors must be positive and sum to 1. The loss matrix must have zeros on the diagonal and positive off-diagonal elements. The splitting index can be gini or information. The default priors are proportional to the data counts, the losses default to 1, and the split defaults to gini. |
| control   | a list of options that control details of the rpart algorithm. See <a href="#">rpart.control</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| cost      | a vector of non-negative costs, one for each variable in the model. Defaults to one for all variables. These are scalings to be applied when considering splits, so the improvement on splitting on a variable is divided by its cost in deciding which split to choose.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| ...       | arguments to <a href="#">rpart.control</a> may also be specified in the call to rpart. They are checked against the list of valid arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Details

This differs from the tree function in S mainly in its handling of surrogate variables. In most details it follows Breiman *et. al* (1984) quite closely. R package **tree** provides a re-implementation of tree.

## Value

An object of class **rpart**. See [rpart.object](#).

## References

Breiman L., Friedman J. H., Olshen R. A., and Stone, C. J. (1984) *Classification and Regression Trees*. Wadsworth.

**See Also**

[rpart.control](#), [rpart.object](#), [summary.rpart](#), [print.rpart](#)

**Examples**

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
 parms = list(prior = c(.65,.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
 control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = NA) # otherwise on some devices the text is clipped
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
```

**rpart.control**

*Control for Rpart Fits*

**Description**

Various parameters that control aspects of the `rpart` fit.

**Usage**

```
rpart.control(minsplit = 20, minbucket = round(minsplit/3), cp = 0.01,
 maxcompete = 4, maxsurrogate = 5, usesurrogate = 2, xval = 10,
 surrogatestyle = 0, maxdepth = 30, ...)
```

**Arguments**

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>minsplit</code>     | the minimum number of observations that must exist in a node in order for a split to be attempted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>minbucket</code>    | the minimum number of observations in any terminal <code>&lt;leaf&gt;</code> node. If only one of <code>minbucket</code> or <code>minsplit</code> is specified, the code either sets <code>minsplit</code> to <code>minbucket*3</code> or <code>minbucket</code> to <code>minsplit/3</code> , as appropriate.                                                                                                                                                                                                                                                                        |
| <code>cp</code>           | complexity parameter. Any split that does not decrease the overall lack of fit by a factor of <code>cp</code> is not attempted. For instance, with anova splitting, this means that the overall R-squared must increase by <code>cp</code> at each step. The main role of this parameter is to save computing time by pruning off splits that are obviously not worthwhile. Essentially, the user informs the program that any split which does not improve the fit by <code>cp</code> will likely be pruned off by cross-validation, and that hence the program need not pursue it. |
| <code>maxcompete</code>   | the number of competitor splits retained in the output. It is useful to know not just which split was chosen, but which variable came in second, third, etc.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>maxsurrogate</code> | the number of surrogate splits retained in the output. If this is set to zero the compute time will be reduced, since approximately half of the computational time (other than setup) is used in the search for surrogate splits.                                                                                                                                                                                                                                                                                                                                                    |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>usesurrogate</code>   | how to use surrogates in the splitting process. 0 means display only; an observation with a missing value for the primary split rule is not sent further down the tree. 1 means use surrogates, in order, to split subjects missing the primary variable; if all surrogates are missing the observation is not split. For value 2 ,if all surrogates are missing, then send the observation in the majority direction. A value of 0 corresponds to the action of <code>tree</code> , and 2 to the recommendations of Breiman <i>et.al</i> (1984). |
| <code>xval</code>           | number of cross-validations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>surrogatestyle</code> | controls the selection of a best surrogate. If set to 0 (default) the program uses the total number of correct classification for a potential surrogate variable, if set to 1 it uses the percent correct, calculated over the non-missing values of the surrogate. The first option more severely penalizes covariates with a large number of missing values.                                                                                                                                                                                    |
| <code>maxdepth</code>       | Set the maximum depth of any node of the final tree, with the root node counted as depth 0. Values greater than 30 <code>rpart</code> will give nonsense results on 32-bit machines.                                                                                                                                                                                                                                                                                                                                                              |
| <code>...</code>            | mop up other arguments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### Value

A list containing the options.

### See Also

[rpart](#)

---

**rpart.exp**

*Initialization function for exponential fitting*

---

### Description

This function does the initialization step for `rpart`, when the response is a survival object. It rescales the data so as to have an exponential baseline hazard and then uses Poisson methods. This function would rarely if ever be called directly by a user.

### Usage

```
rpart.exp(y, offset, parms, wt)
```

### Arguments

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>y</code>      | the response, which will be of class <code>Surv</code>                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>offset</code> | optional offset                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>parms</code>  | parameters controlling the fit. This is a list with components <code>shrink</code> and <code>method</code> . The first is the prior for the coefficient of variation of the predictions. The second is either "deviance" or "sqrt" and is the measure used for cross-validation. If values are missing the defaults are used, which are "deviance" for the method, and a shrinkage of 1.0 for the deviance method and 0 for the square root. |
| <code>wt</code>     | case weights, if present                                                                                                                                                                                                                                                                                                                                                                                                                     |

|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| frame  | data frame with one row for each node in the tree. The <code>row.names</code> of <code>frame</code> contain the (unique) node numbers that follow a binary ordering indexed by node depth. Columns of <code>frame</code> include <code>var</code> , a factor giving the names of the variables used in the split at each node (leaf nodes are denoted by the level "<leaf>"), <code>n</code> , the number of observations reaching the node, <code>wt</code> , the sum of case weights for observations reaching the node, <code>dev</code> , the deviance of the node, <code>yval</code> , the fitted value of the response at the node, and <code>splits</code> , a two column matrix of left and right split labels for each node. Also included in the frame are <code>complexity</code> , the complexity parameter at which this split will collapse, <code>ncompet</code> , the number of competitor splits recorded, and <code>nsurrogate</code> , the number of surrogate splits recorded.<br>Extra response information which may be present is in <code>yval2</code> , which contains the number of events at the node (poisson tree), or a matrix containing the fitted class, the class counts for each node and the class probabilities (classification trees). |
| where  | an integer vector of the same length as the number of observations in the root node, containing the row number of <code>frame</code> corresponding to the leaf node that each observation falls into.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| call   | an image of the call that produced the object, but with the arguments all named and with the actual formula included as the <code>formula</code> argument. To re-evaluate the call, say <code>update(tree)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| terms  | an object of class <code>c("terms", "formula")</code> (see <a href="#">terms.object</a> ) summarizing the formula. Used by various methods, but typically not of direct relevance to users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| splits | a numeric matrix describing the splits: only present if there are any. The row label is the name of the split variable, and columns are <code>count</code> , the number of observations (which are not missing and are of positive weight) sent left or right by the split (for competitor splits this is the number that would have been sent left or right had this split been used, for surrogate splits it is the number missing the primary split variable which were decided using this surrogate), <code>ncat</code> ,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

the number of categories or levels for the variable (+/-1 for a continuous variable), `improve`, which is the improvement in deviance given by this split, or, for surrogates, the concordance of the surrogate with the primary, and `index`, the numeric split point. The last column `adj` gives the adjusted concordance for surrogate splits. For a factor, the `index` column contains the row number of the `csplit` matrix. For a continuous variable, the sign of `ncat` determines whether the subset `x < cutpoint` or `x > cutpoint` is sent to the left.

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>csplit</code>              | an integer matrix. (Only present only if at least one of the split variables is a factor or ordered factor.) There is a row for each such split, and the number of columns is the largest number of levels in the factors. Which row is given by the <code>index</code> column of the <code>splits</code> matrix. The columns record 1 if that level of the factor goes to the left, 3 if it goes to the right, and 2 if that level is not present at this node of the tree (or not defined for the factor). |
| <code>method</code>              | character string: the method used to grow the tree. One of "class", "exp", "poisson", "anova" or "user" (if splitting functions were supplied).                                                                                                                                                                                                                                                                                                                                                              |
| <code>cptable</code>             | a matrix of information on the optimal prunings based on a complexity parameter.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>variable.importance</code> | a named numeric vector giving the importance of each variable. (Only present if there are any splits.) When printed by <code>summary.rpart</code> these are rescaled to add to 100.                                                                                                                                                                                                                                                                                                                          |
| <code>numresp</code>             | integer number of responses; the number of levels for a factor response.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>parms, control</code>      | a record of the arguments supplied, which defaults filled in.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>functions</code>           | the <code>summary</code> , <code>print</code> and <code>text</code> functions for method used.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>ordered</code>             | a named logical vector recording for each variable if it was an ordered factor.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>na.action</code>           | (where relevant) information returned by <code>model.frame</code> on the special handling of NAs derived from the <code>na.action</code> argument.                                                                                                                                                                                                                                                                                                                                                           |

There may be `attributes` "xlevels" and "levels" recording the levels of any factor splitting variables and of a factor response respectively.

Optional components include the model frame (`model`), the matrix of predictors (`x`) and the response variable (`y`) used to construct the `rpart` object.

## Structure

The following components must be included in a legitimate `rpart` object.

*Plots the Approximate R-Square for the Different Splits*

## Description

Produces 2 plots. The first plots the r-square (apparent and apparent - from cross-validation) versus the number of splits. The second plots the Relative Error(cross-validation) +/- 1-SE from cross-validation versus the number of splits.

**Usage**

```
rsq.rpart(x)
```

**Arguments**

- x fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.

**Side Effects**

Two plots are produced.

**Note**

The labels are only appropriate for the "anova" method.

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
rsq.rpart(z.auto)
```

---

snip.rpart

*Snip Subtrees of an Rpart Object*

---

**Description**

Creates a "snipped" rpart object, containing the nodes that remain after selected subtrees have been snipped off. The user can snip nodes using the toss argument, or interactively by clicking the mouse button on specified nodes within the graphics window.

**Usage**

```
snip.rpart(x, toss)
```

**Arguments**

- x fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
- toss an integer vector containing indices (node numbers) of all subtrees to be snipped off. If missing, user selects branches to snip off as described below.

**Details**

A dendrogram of rpart is expected to be visible on the graphics device, and a graphics input device (e.g., a mouse) is required. Clicking (the selection button) on a node displays the node number, sample size, response y-value, and Error (dev). Clicking a second time on the same node snips that subtree off and visually erases the subtree. This process may be repeated an number of times. Warnings result from selecting the root or leaf nodes. Clicking the exit button will stop the snipping process and return the resulting rpart object.

See the documentation for the specific graphics device for details on graphical input techniques.

**Value**

A rpart object containing the nodes that remain after specified or selected subtrees have been snipped off.

**Warning**

Visually erasing the plot is done by over-plotting with the background colour. This will do nothing if the background is transparent (often true for screen devices).

**See Also**

[plot.rpart](#)

**Examples**

```
dataset not in R
Not run:
z.survey <- rpart(market.survey) # grow the rpart object
plot(z.survey) # plot the tree
z.survey2 <- snip.rpart(z.survey, toss = 2) # trim subtree at node 2
plot(z.survey2) # plot new tree

can also interactively select the node using the mouse in the
graphics window

End(Not run)
```

**Description**

The solder data frame has 720 rows and 6 columns, representing a balanced subset of a designed experiment varying 5 factors on the soldering of components on printed-circuit boards.

**Usage**

solder

**Format**

This data frame contains the following columns:

**Opening** a factor with levels ‘L’, ‘M’ and ‘S’ indicating the amount of clearance around the mounting pad.

**Solder** a factor with levels ‘Thick’ and ‘Thin’ giving the thickness of the solder used.

**Mask** a factor with levels ‘A1.5’, ‘A3’, ‘B3’ and ‘B6’ indicating the type and thickness of mask used.

**PadType** a factor with levels ‘D4’, ‘D6’, ‘D7’, ‘L4’, ‘L6’, ‘L7’, ‘L8’, ‘L9’, ‘W4’ and ‘W9’ giving the size and geometry of the mounting pad.

**Panel** 1:3 indicating the panel on a board being tested.

**skips** a numeric vector giving the number of visible solder skips.

**Source**

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA.

**Examples**

```
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
 data = solder, method = "anova")
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```

---

stagec

*Stage C Prostate Cancer*

---

**Description**

A set of 146 patients with stage C prostate cancer, from a study exploring the prognostic value of flow cytometry.

**Usage**

```
data(stagec)
```

**Format**

A data frame with 146 observations on the following 8 variables.

pgtime Time to progression or last follow-up (years)  
pgstat 1 = progression observed, 0 = censored  
age age in years  
eet early endocrine therapy, 1 = no, 2 = yes  
g2 percent of cells in G2 phase, as found by flow cytometry  
grade grade of the tumor, Farrow system  
gleason grade of the tumor, Gleason system  
ploidy the ploidy status of the tumor, from flow cytometry. Values are 'diploid', 'tetraploid', and 'aneuploid'

**Details**

A tumor is called diploid (normal complement of dividing cells) if the fraction of cells in G2 phase was determined to be 13% or less. Aneuploid cells have a measurable fraction with a chromosome count that is neither 24 nor 48, for these the G2 percent is difficult or impossible to measure.

**Examples**

```
require(survival)
rpart(Surv(pgtime, pgstat) ~ ., stagec)
```

**summary.rpart**      *Summarize a Fitted Rpart Object*

## Description

Returns a detailed listing of a fitted **rpart** object.

## Usage

```
S3 method for class 'rpart'
summary(object, cp = 0, digits = getOption("digits"), file, ...)
```

## Arguments

|               |                                                                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b> | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <b>rpart</b> function. |
| <b>digits</b> | Number of significant digits to be used in the result.                                                                                                                                        |
| <b>cp</b>     | trim nodes with a complexity of less than <b>cp</b> from the listing.                                                                                                                         |
| <b>file</b>   | write the output to a given file name. (Full listings of a tree are often quite long).                                                                                                        |
| ...           | arguments to be passed to or from other methods.                                                                                                                                              |

## Details

This function is a method for the generic function **summary** for class "rpart". It can be invoked by calling **summary** for an object of the appropriate class, or directly by calling **summary.rpart** regardless of the class of the object.

It prints the call, the table shown by **printcp**, the variable importance (summing to 100) and details for each node (the details depending on the type of tree).

## Examples

```
a regression tree
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)

a classification tree with multiple variables and surrogate splits.
summary(rpart(Kyphosis ~ Age + Number + Start, data = kyphosis))
```

---

text.rpart*Place Text on a Dendrogram Plot*

---

**Description**

Labels the current plot of the tree dendrogram with text.

**Usage**

```
S3 method for class 'rpart'
text(x, splits = TRUE, label, FUN = text, all = FALSE,
 pretty = NULL, digits = getOption("digits") - 3, use.n = FALSE,
 fancy = FALSE, fwidth = 0.8, fheight = 0.8, bg = par("bg"),
 minlength = 1L, ...)
```

**Arguments**

|                  |                                                                                                                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>         | fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.                                                                                      |
| <b>splits</b>    | logical flag. If TRUE (default), then the splits in the tree are labeled with the criterion for the split.                                                                                                                                                                               |
| <b>label</b>     | For compatibility with <code>rpart2</code> , ignored in this version (with a warning).                                                                                                                                                                                                   |
| <b>FUN</b>       | the name of a labeling function, e.g. <code>text</code> .                                                                                                                                                                                                                                |
| <b>all</b>       | Logical. If TRUE, all nodes are labeled, otherwise just terminal nodes.                                                                                                                                                                                                                  |
| <b>minlength</b> | the length to use for factor labels. A value of 1 causes them to be printed as 'a', 'b', ..... Larger values use abbreviations of the label names. See the <code>labels.rpart</code> function for details.                                                                               |
| <b>pretty</b>    | an alternative to the <code>minlength</code> argument, see <a href="#">labels.rpart</a> .                                                                                                                                                                                                |
| <b>digits</b>    | number of significant digits to include in numerical labels.                                                                                                                                                                                                                             |
| <b>use.n</b>     | Logical. If TRUE, adds to label (\#events level1/ \#events level2/etc. for <code>class</code> , <code>n</code> for <code>anova</code> , and \#events/n for <code>poisson</code> and <code>exp</code> ).                                                                                  |
| <b>fancy</b>     | Logical. If TRUE, nodes are represented by ellipses (interior nodes) and rectangles (leaves) and labeled by <code>yval</code> . The edges connecting the nodes are labeled by left and right splits.                                                                                     |
| <b>fwidth</b>    | Relates to option <code>fancy</code> and the width of the ellipses and rectangles. If <code>fwidth &lt; 1</code> then it is a scaling factor (default = 0.8). If <code>fwidth &gt; 1</code> then it represents the number of character widths (for current graphical device) to use.     |
| <b>fheight</b>   | Relates to option <code>fancy</code> and the height of the ellipses and rectangles. If <code>fheight &lt; 1</code> then it is a scaling factor (default = 0.8). If <code>fheight &gt; 1</code> then it represents the number of character heights (for current graphical device) to use. |
| <b>bg</b>        | The color used to paint the background to annotations if <code>fancy = TRUE</code> .                                                                                                                                                                                                     |
| <b>...</b>       | Graphical parameters may also be supplied as arguments to this function (see <code>par</code> ). As labels often extend outside the plot region it can be helpful to specify <code>xpd = TRUE</code> .                                                                                   |

### Side Effects

the current plot of a tree dendrogram is labeled.

### See Also

[text](#), [plot.rpart](#), [rpart](#), [labels.rpart](#), [abbreviate](#)

### Examples

```
freen.tr <- rpart(y ~ ., freeny)
par(xpd = TRUE)
plot(freen.tr)
text(freen.tr, use.n = TRUE, all = TRUE)
```

**xpred.rpart**

*Return Cross-Validated Predictions*

### Description

Gives the predicted values for an [rpart](#) fit, under cross validation, for a set of complexity parameter values.

### Usage

```
xpred.rpart(fit, xval = 10, cp, return.all = FALSE)
```

### Arguments

|                         |                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>fit</code>        | a object of class "rpart".                                                                                                |
| <code>xval</code>       | number of cross-validation groups. This may also be an explicit list of integers that define the cross-validation groups. |
| <code>cp</code>         | the desired list of complexity values. By default it is taken from the cptable component of the fit.                      |
| <code>return.all</code> | if FALSE return only the first element of the prediction                                                                  |

### Details

Complexity penalties are actually ranges, not values. If the cp values found in the table were .36, .28, and .13, for instance, this means that the first row of the table holds for all complexity penalties in the range [.36, 1], the second row for cp in the range [.28, .36) and the third row for [.13, .28). By default, the geometric mean of each interval is used for cross validation.

### Value

A matrix with one row for each observation and one column for each complexity value. If `return.all` is TRUE and the prediction for each node is a vector, then the result will be an array containing all of the predictions. When the response is categorical, for instance, the result contains the predicted class followed by the class probabilities of the selected terminal node; `result[1, ]` will be the matrix of predicted classes, `result[2, , ]` the matrix of class 1 probabilities, etc.

**See Also**[rpart](#)**Examples**

```
fit <- rpart(Mileage ~ Weight, car.test.frame)
xmat <- xpred.rpart(fit)
xerr <- (xmat - car.test.frame$Mileage)^2
apply(xerr, 2, sum) # cross-validated error estimate

approx same result as rel. error from printcp(fit)
apply(xerr, 2, sum)/var(car.test.frame$Mileage)
printcp(fit)
```

*xpred.rpart*

# Chapter 28

## The spatial package

---

`anova.trls`

*Anova tables for fitted trend surface objects*

---

### Description

Compute analysis of variance tables for one or more fitted trend surface model objects; where `anova.trls` is called with multiple objects, it passes on the arguments to `anovalist.trls`.

### Usage

```
S3 method for class 'trls'
anova(object, ...)
anovalist.trls(object, ...)
```

### Arguments

|                     |                                                               |
|---------------------|---------------------------------------------------------------|
| <code>object</code> | A fitted trend surface model object from <code>surf.ls</code> |
| <code>...</code>    | Further objects of the same kind                              |

### Value

`anova.trls` and `anovalist.trls` return objects corresponding to their printed tabular output.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

[surf.ls](#)

## Examples

```
library(stats)
data(topo, package="MASS")
topo0 <- surf.ls(0, topo)
topo1 <- surf.ls(1, topo)
topo2 <- surf.ls(2, topo)
topo3 <- surf.ls(3, topo)
topo4 <- surf.ls(4, topo)
anova(topo0, topo1, topo2, topo3, topo4)
summary(topo4)
```

**correlogram**

*Compute Spatial Correlograms*

## Description

Compute spatial correlograms of spatial data or residuals.

## Usage

```
correlogram(krig, nint, plotit = TRUE, ...)
```

## Arguments

|        |                                                          |
|--------|----------------------------------------------------------|
| krig   | trend-surface or kriging object with columns x, y, and z |
| nint   | number of bins used                                      |
| plotit | logical for plotting                                     |
| ...    | parameters for the plot                                  |

## Details

Divides range of data into `nint` bins, and computes the covariance for pairs with separation in each bin, then divides by the variance. Returns results for bins with 6 or more pairs.

## Value

`x` and `y` coordinates of the correlogram, and `cnt`, the number of pairs averaged per bin.

## Side Effects

Plots the correlogram if `plotit = TRUE`.

lines(d, expcov(d, 0.7))
```

---

expcov

*Spatial Covariance Functions*

---

## Description

Spatial covariance functions for use with `surf.gls`.

## Usage

```
expcov(r, d, alpha = 0, se = 1)
gaucov(r, d, alpha = 0, se = 1)
sphercov(r, d, alpha = 0, se = 1, D = 2)
```

## Arguments

|       |                                                         |
|-------|---------------------------------------------------------|
| r     | vector of distances at which to evaluate the covariance |
| d     | range parameter                                         |
| alpha | proportion of nugget effect                             |
| se    | standard deviation at distance zero                     |
| D     | dimension of spheres.                                   |

## Value

vector of covariance values.

```

---

Kaver*Average K-functions from Simulations*

---

## Description

Forms the average of a series of (usually simulated) K-functions.

## Usage

```
Kaver(fs, nsim, ...)
```

## Arguments

|      |                                                |
|------|------------------------------------------------|
| fs   | full scale for K-fn                            |
| nsim | number of simulations                          |
| ...  | arguments to simulate one point process object |

## Value

list with components x and y of the average K-fn on L-scale.

## References

Ripley, B. D. (1981) *Spatial Statistics*. Wiley.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**Kfn***Compute K-fn of a Point Pattern***Description**

Actually computes  $L = \sqrt{K/\pi}$ .

**Usage**

```
Kfn(pp, fs, k=100)
```

**Arguments**

|                 |                                                                                    |
|-----------------|------------------------------------------------------------------------------------|
| <code>pp</code> | a list such as a pp object, including components <code>x</code> and <code>y</code> |
| <code>fs</code> | full scale of the plot                                                             |
| <code>k</code>  | number of regularly spaced distances in (0, <code>fs</code> )                      |

**Details**

relies on the domain D having been set by `ppinit` or `ppregion`.

**Value**

A list with components

|                   |                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------|
| <code>x</code>    | vector of distances                                                                            |
| <code>y</code>    | vector of L-fn values                                                                          |
| <code>k</code>    | number of distances returned – may be less than <code>k</code> if <code>fs</code> is too large |
| <code>dmin</code> | minimum distance between pair of points                                                        |
| <code>lm</code>   | maximum deviation from $L(t) = t$                                                              |

---

`ppgetregion`*Get Domain for Spatial Point Pattern Analyses*

---

**Description**

Retrieves the rectangular domain  $(x_l, x_u) \times (y_l, y_u)$  from the underlying C code.

**Usage**`ppgetregion()`**Value**

A vector of length four with names `c("x1", "xu", "y1", "yu")`.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**See Also**`ppregion`

---

`ppinit`*Read a Point Process Object from a File*

---

**Description**

Read a file in standard format and create a point process object.

**Usage**`ppinit(file)`**Arguments**

`file`            string giving file name

**Details**

The file should contain  
the number of points  
a header (ignored)  
`xl xu yl yu scale`  
`x y` (repeated n times)

**Value**

class "pp" object with components `x, y, xl, xu, yl, yu`

### Side Effects

Calls `ppregion` to set the domain.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

### See Also

[ppregion](#)

### Examples

```
towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="b", xlab="distance", ylab="L(t)")
```

### Description

Pseudo-likelihood estimation of a Strauss spatial point process.

### Usage

```
pplik(pp, R, ng=50, trace=FALSE)
```

### Arguments

|                    |                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| <code>pp</code>    | a <code>pp</code> object                                                                                         |
| <code>R</code>     | the fixed parameter <code>R</code>                                                                               |
| <code>ng</code>    | use a <code>ng</code> x <code>ng</code> grid with border <code>R</code> in the domain for numerical integration. |
| <code>trace</code> | logical? Should function evaluations be printed?                                                                 |

### Value

estimate for `c` in the interval [0, 1].

### References

```

---

**ppregion***Set Domain for Spatial Point Pattern Analyses*

---

**Description**

Sets the rectangular domain  $(x_l, x_u) \times (y_l, y_u)$ .

**Usage**

```
ppregion(xl = 0, xu = 1, yl = 0, yu = 1)
```

**Arguments**

|    |                                                                                           |
|----|-------------------------------------------------------------------------------------------|
| xl | Either xl or a list containing components xl, xu, yl, yu (such as a point-process object) |
| xu |                                                                                           |
| yl |                                                                                           |
| yu |                                                                                           |

**Value**

none

**Side Effects**

initializes variables in the C subroutines.

---

**predict.trls***Predict method for trend surface fits*

---

**Description**

Predicted values based on trend surface model object

**Usage**

```
S3 method for class 'trls'
predict(object, x, y, ...)
```

**Arguments**

- object** Fitted trend surface model object returned by `surf.ls`  
**x** Vector of prediction location eastings (x coordinates)  
**y** Vector of prediction location northings (y coordinates)  
**...** further arguments passed to or from other methods.

**Value**

`predict.trls` produces a vector of predictions corresponding to the prediction locations. To display the output with `image` or `contour`, use `trmat` or convert the returned vector to matrix form.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**See Also**

`surf.ls`, `trmat`

**Examples**

```
data(topo, package="MASS")
topo2 <- surf.ls(2, topo)
topo4 <- surf.ls(4, topo)
x <- c(1.78, 2.21)
y <- c(6.15, 6.15)
z2 <- predict(topo2, x, y)
z4 <- predict(topo4, x, y)
cat("2nd order predictions:", z2, "\n4th order predictions:", z4, "\n")
```

**Description**

Evaluate Kriging surface over a grid.

**Usage**

```
prmat(obj, xl, xu, yl, yu, n)
```

**Arguments**

- obj** object returned by `surf.gls`  
**xl** limits of the rectangle for grid  
**xu**  
**yl**  
**yu**  
**n** use  $n \times n$  grid within the rectangle

**Value**

list with components `x`, `y` and `z` suitable for `contour` and `image`.

**References**

Ripley, B. D. (1981) *Spatial Statistics*. Wiley.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**See Also**

`surf.gls`, `trmat`, `semat`

**Examples**

```
data(topo, package="MASS")
topo.kr <- surf.gls(2, expcov, topo, d=0.7)
prsurf <- prmat(topo.kr, 0, 6.5, 0, 6.5, 50)
contour(prsurf, levels=seq(700, 925, 25))
```

---

Psim

*Simulate Binomial Spatial Point Process*

---

**Description**

Simulate Binomial spatial point process.

**Usage**

`Psim(n)`

**Arguments**

`n` number of points

**Details**

relies on the region being set by `ppinit` or `ppregion`.

**Value**

list of vectors of `x` and `y` coordinates.

**Side Effects**

uses the random number generator.

**References**

Ripley, B. D. (1981) *Spatial Statistics*. Wiley.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**See Also**

**Examples**

```
towns <- ppinit("towns.dat")
par(pty="s")
plot(Kfn(towns, 10), type="s", xlab="distance", ylab="L(t)")
for(i in 1:10) lines(Kfn(Psim(69), 10))
```

semat

*Evaluate Kriging Standard Error of Prediction over a Grid*

**Description**

Evaluate Kriging standard error of prediction over a grid.

**Usage**

```
semat(obj, xl, xu, yl, yu, n, se)
```

**Arguments**

|     |                                                                                                                                                         |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| obj | object returned by <code>surf.gls</code>                                                                                                                |
| xl  | limits of the rectangle for grid                                                                                                                        |
| xu  |                                                                                                                                                         |
| yl  |                                                                                                                                                         |
| yu  |                                                                                                                                                         |
| n   | use $n \times n$ grid within the rectangle                                                                                                              |
| se  | standard error at distance zero as a multiple of the supplied covariance. Otherwise estimated, and it assumed that a correlation function was supplied. |

**Value**

list with components x, y and z suitable for `contour` and `image`.

**References**

- Ripley, B. D. (1981) *Spatial Statistics*. Wiley.  
 Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

contour(prsurf, levels=seq(700, 925, 25))
sesurf <- semat(topo.kr, 0, 6.5, 0, 6.5, 30)
contour(sesurf, levels=c(22,25))
```

---

SSI

*Simulates Sequential Spatial Inhibition Point Process*

---

## Description

Simulates SSI (sequential spatial inhibition) point process.

## Usage

```
SSI(n, r)
```

## Arguments

|   |                     |
|---|---------------------|
| n | number of points    |
| r | inhibition distance |

## Details

uses the region set by ppinit or ppregion.

## Value

list of vectors of x and y coordinates

## Side Effects

uses the random number generator.

## Warnings

will never return if r is too large and it cannot place n points.

## References

Ripley, B. D. (1981) *Spatial Statistics*. Wiley.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

## See Also

## Examples

```
towns <- ppinit("towns.dat")
par(pty = "s")
plot(Kfn(towns, 10), type = "b", xlab = "distance", ylab = "L(t)")
lines(Kaver(10, 25, SSI(69, 1.2)))
```

Strauss

*Simulates Strauss Spatial Point Process*

## Description

Simulates Strauss spatial point process.

## Usage

```
Strauss(n, c=0, r)
```

## Arguments

|   |                                                                                       |
|---|---------------------------------------------------------------------------------------|
| n | number of points                                                                      |
| c | parameter c in [0, 1]. c = 0 corresponds to complete inhibition at distances up to r. |
| r | inhibition distance                                                                   |

## Details

Uses spatial birth-and-death process for  $4n$  steps, or for  $40n$  steps starting from a binomial pattern on the first call from an other function. Uses the region set by ppinit or ppregion.

## Value

list of vectors of  $x$  and  $y$  coordinates

## Side Effects

uses the random number generator

## References

**surf.gls***Fits a Trend Surface by Generalized Least-squares*

---

**Description**

Fits a trend surface by generalized least-squares.

**Usage**

```
surf.gls(np, covmod, x, y, z, nx = 1000, ...)
```

**Arguments**

|        |                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------|
| np     | degree of polynomial surface                                                                            |
| covmod | function to evaluate covariance or correlation function                                                 |
| x      | x coordinates or a data frame with columns x, y, z                                                      |
| y      | y coordinates                                                                                           |
| z      | z coordinates. Will supersede x\$z                                                                      |
| nx     | Number of bins for table of the covariance. Increasing adds accuracy, and increases size of the object. |
| ...    | parameters for covmod                                                                                   |

**Value**

list with components

|      |                                   |
|------|-----------------------------------|
| beta | the coefficients                  |
| x    |                                   |
| y    |                                   |
| z    | and others for internal use only. |

title(xlab= "Circle radius proportional to Cook's influence statistic")
```

### trls.influence

*Regression diagnostics for trend surfaces*

## Description

This function provides the basic quantities which are used in forming a variety of diagnostics for checking the quality of regression fits for trend surfaces calculated by `surf.ls`.

## Usage

```
trls.influence(object)
S3 method for class 'trls'
plot(x, border = "red", col = NA, pch = 4, cex = 0.6,
 add = FALSE, div = 8, ...)
```

## Arguments

|                            |                                                                     |
|----------------------------|---------------------------------------------------------------------|
| object, x                  | Fitted trend surface model from <code>surf.ls</code>                |
| div                        | scaling factor for influence circle radii in <code>plot.trls</code> |
| add                        | add influence plot to existing graphics if TRUE                     |
| border, col, pch, cex, ... | additional graphical parameters                                     |

## Value

`trls.influence` returns a list with components:

|         |                                                       |
|---------|-------------------------------------------------------|
| r       | raw residuals as given by <code>residuals.trls</code> |
| hii     | diagonal elements of the Hat matrix                   |
| stresid | standardised residuals                                |
| Di      | Cook's statistic                                      |

trsurf <- trmat(topo.kr, 0, 6.5, 0, 6.5, 50)
```

---

variogram

*Compute Spatial Variogram*

---

## Description

Compute spatial (semi-)variogram of spatial data or residuals.

## Usage

```
variogram(krig, nint, plotit = TRUE, ...)
```

## Arguments

|        |                                                          |
|--------|----------------------------------------------------------|
| krig   | trend-surface or kriging object with columns x, y, and z |
| nint   | number of bins used                                      |
| plotit | logical for plotting                                     |
| ...    | parameters for the plot                                  |

## Details

Divides range of data into `nint` bins, and computes the average squared difference for pairs with separation in each bin. Returns results for bins with 6 or more pairs.

## Value

`x` and `y` coordinates of the variogram and `cnt`, the number of pairs averaged per bin.

## Side Effects

Plots the variogram if `plotit = TRUE`

---

aareg

*Aalen's additive regression model for censored data*

---

### Description

Returns an object of class "aareg" that represents an Aalen model.

### Usage

```
aareg(formula, data, weights, subset, na.action,
 qrtol=1e-07, nmin, dfbeta=FALSE, taper=1,
 test = c('aalen', 'variance', 'nrisk'),
 model=FALSE, x=FALSE, y=FALSE)
```

### Arguments

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula | a formula object, with the response on the left of a ‘~’ operator and the terms, separated by + operators, on the right. The response must be a Surv object. Due to a particular computational approach that is used, the model MUST include an intercept term. If "-1" is used in the model formula the program will ignore it.                                                                                                                                                       |
| data    | data frame in which to interpret the variables named in the formula, subset, and weights arguments. This may also be a single number to handle some special cases – see below for details. If data is missing, the variables in the model formula should be in the search path.                                                                                                                                                                                                        |
| weights | vector of observation weights. If supplied, the fitting algorithm minimizes the sum of the weights multiplied by the squared residuals (see below for additional technical details). The length of weights must be the same as the number of observations. The weights must be nonnegative and it is recommended that they be strictly positive, since zero weights are ambiguous. To exclude particular observations from the model, use the subset argument instead of zero weights. |
| subset  | expression specifying which subset of observations should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating the observation numbers to be included, or a character vector of the observation names that should be included. All observations are included by default.                                                                                                             |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| na.action   | a function to filter missing data. This is applied to the model frame after any subset argument has been applied. The default is na.fail, which returns an error if any missing values are found. An alternative is na.exclude, which deletes observations that contain one or more missing values.                                                                                                                                                                                                                                                                                                                                       |
| qr_tol      | tolerance for detection of singularity in the QR decomposition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| nmin        | minimum number of observations for an estimate; defaults to 3 times the number of covariates. This essentially truncates the computations near the tail of the data set, when n is small and the calculations can become numerically unstable.                                                                                                                                                                                                                                                                                                                                                                                            |
| dfbeta      | should the array of dfbeta residuals be computed. This implies computation of the sandwich variance estimate. The residuals will always be computed if there is a cluster term in the model formula.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| taper       | allows for a smoothed variance estimate. Var(x), where x is the set of covariates, is an important component of the calculations for the Aalen regression model. At any given time point t, it is computed over all subjects who are still at risk at time t. The taper argument allows smoothing these estimates, for example taper=(1:4)/4 would cause the variance estimate used at any event time to be a weighted average of the estimated variance matrices at the last 4 death times, with a weight of 1 for the current death time and decreasing to 1/4 for prior event times. The default value gives the standard Aalen model. |
| test        | selects the weighting to be used, for computing an overall "average" coefficient vector over time and the subsequent test for equality to zero.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| model, x, y | should copies of the model frame, the x matrix of predictors, or the response vector y be included in the saved result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Details

The Aalen model assumes that the cumulative hazard  $H(t)$  for a subject can be expressed as  $a(t) + X B(t)$ , where  $a(t)$  is a time-dependent intercept term,  $X$  is the vector of covariates for the subject (possibly time-dependent), and  $B(t)$  is a time-dependent matrix of coefficients. The estimates are inherently non-parametric; a fit of the model will normally be followed by one or more plots of the estimates.

The estimates may become unstable near the tail of a data set, since the increment to  $B$  at time  $t$  is based on the subjects still at risk at time  $t$ . The tolerance and/or nmin parameters may act to truncate the estimate before the last death. The taper argument can also be used to smooth out the tail of the curve. In practice, the addition of a taper such as 1:10 appears to have little effect on death times when n is still reasonably large, but can considerably dampen wild oscillations in the tail of the plot.

## Value

an object of class "aareg" representing the fit, with the following components:

|                |                                                                                                                                                |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| n              | vector containing the number of observations in the data set, the number of event times, and the number of event times used in the computation |
| times          | vector of sorted event times, which may contain duplicates                                                                                     |
| nrisk          | vector containing the number of subjects at risk, of the same length as times                                                                  |
| coefficient    | matrix of coefficients, with one row per event and one column per covariate                                                                    |
| test.statistic | the value of the test statistic, a vector with one element per covariate                                                                       |
| test.var       | variance-covariance matrix for the test                                                                                                        |
| test           | the type of test; a copy of the test argument above                                                                                            |
| tweight        | matrix of weights used in the computation, one row per event                                                                                   |
| call           | a copy of the call that produced this result                                                                                                   |

**anova.coxpath***Analysis of Deviance for a Cox model.***Description**

Compute an analysis of deviance table for one or more Cox model fits.

**Usage**

```
S3 method for class 'coxph'
anova(object, ..., test = 'Chisq')
```

**Arguments**

|        |                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------|
| object | An object of class coxph                                                                                 |
| ...    | Further coxph objects                                                                                    |
| test   | a character string. The appropriate test is a chisquare, all other choices result in no test being done. |

## Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the model log-likelihood as each term of the formula is added in turn are given in as the rows of a table, plus the log-likelihoods themselves. A robust variance estimate is normally used in situations where the model may be mis-specified, e.g., multiple events per subject. In this case a comparison of partial-likelihood values does not make sense, and `anova` will refuse to print results.

If more than one object is specified, the table has a row for the degrees of freedom and loglikelihood for each model. For all but the first model, the change in degrees of freedom and loglik is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in loglik for each row.

## Value

An object of class "anova" inheriting from class "data.frame".

## Warning

The comparison between two or more models by `anova` or `will` only be valid if they are fitted to the same dataset. This may be a problem if there are missing values.

## See Also

[coxph](#), [anova](#).

## Examples

```
fit <- coxph(Surv(futime, fustat) ~ resid.ds *rx + ecog.ps, data = ovarian)
anova(fit)
fit2 <- coxph(Surv(futime, fustat) ~ resid.ds +rx + ecog.ps, data=ovarian)
anova(fit2,fit)
```

---

attrassign

*Create new-style "assign" attribute*

---

## Description

The "assign" attribute on model matrices describes which columns come from which terms in the model formula. It has two versions. R uses the original version, but the alternate version found in S-plus is sometimes useful.

## Usage

```
Default S3 method:
attrassign(object, tt,...)
S3 method for class 'lm'
attrassign(object,...)
```

### Arguments

|        |                                     |
|--------|-------------------------------------|
| object | model matrix or linear model object |
| tt     | terms object                        |
| ...    | ignored                             |

### Details

For instance consider the following

```
survreg(Surv(time, status) ~ age + sex + factor(ph.ecog), lung)
```

R gives the compact for assign, a vector (0, 1, 2, 3, 3, 3); which can be read as “the first column of the X matrix (intercept) goes with none of the terms, the second column of X goes with term 1 of the model equation, the third column of X with term 2, and columns 4-6 with term 3”.

The alternate (S-Plus default) form is a list

```
$(Intercept) 1
$age 2
$sex 3
$factor(ph.ecog) 4 5 6
```

### Value

A list with names corresponding to the term names and elements that are vectors indicating which columns come from which terms

### See Also

[terms](#), [model.matrix](#)

### Examples

```
formula <- Surv(time,status)~factor(ph.ecog)
tt <- terms(formula)
mf <- model.frame(tt,data=lung)
mm <- model.matrix(tt,mf)
a few rows of data
mm[1:3,]
old-style assign attribute
attr(mm,"assign")
alternate style assign attribute
attrassign(mm,tt)
```

---

|         |                                                            |
|---------|------------------------------------------------------------|
| basehaz | <i>Compute the baseline survival curve for a Cox model</i> |
|---------|------------------------------------------------------------|

---

## Description

Compute the baseline survival curve for a Cox model.

## Usage

```
basehaz(fit, centered = TRUE)
```

## Arguments

- |          |                                                                                                                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fit      | The result of a coxph fit.                                                                                                                                                                             |
| centered | If TRUE, the resultant curve is for a hypothetical subject whose covariate values are the corresponding means from the original data, otherwise for a hypothetical subject with a mean vector of zero. |

## Details

This function exists primarily because users will look for the phrase 'baseline hazard' (often SAS converts looking for familiar keywords.) The primary function for creating a survival curve is survfit, which this calls. See that manual page for more options, including confidence limits and the ability to use other covariate vectors. The result of survfit also has print, plot and summary methods that make it far more useful.

## Value

a data frame with components

- |        |                                                                                             |
|--------|---------------------------------------------------------------------------------------------|
| time   | The sorted vector of unique time points (those at which an event occurred)                  |
| hazard | The baseline hazard function                                                                |
| strata | If fit was a stratified Cox model, the strata. There will be one survival curve per strata. |

**bladder***Bladder Cancer Recurrences*

---

**Description**

Data on recurrences of bladder cancer, used by many people to demonstrate methodology for recurrent event modelling.

Bladder1 is the full data set from the study. It contains all three treatment arms and all recurrences for 118 subjects; the maximum observed number of recurrences is 9.

Bladder is the data set that appears most commonly in the literature. It uses only the 85 subjects with nonzero follow-up who were assigned to either thiotepa or placebo. The status variable is 1 for recurrence and 0 for everything else (including death for any reason). The data set is laid out in the competing risks format of the paper by Wei, Lin, and Weissfeld.

Bladder2 uses the same subset of subjects as bladder, but formatted in the (start, stop] or Anderson-Gill style. Note that in transforming from the WLW to the AG style data set there is a quite common programming mistake that leads to extra follow-up time for 12 subjects (all those with more than 4 recurrences); this includes some earlier releases of the data in R.

**Usage**

```
bladder1
bladder
bladder2
```

**Format**

bladder1

|             |                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------|
| id:         | Patient id                                                                                                   |
| treatment:  | Placebo, pyridoxine (vitamin B6), or thiotepa                                                                |
| number:     | Initial number of tumours (8=8 or more)                                                                      |
| size:       | Size (cm) of largest initial tumour                                                                          |
| recur:      | Number of recurrences                                                                                        |
| start,stop: | The start and end time of each time interval                                                                 |
| status:     | End of interval code, 0=censored, 1=recurrence,<br>2=death from bladder disease, 3=death other/unknown cause |
| rtumor:     | Number of tumors found at the time of a recurrence                                                           |
| rsize:      | Size of largest tumor at a recurrence                                                                        |

**cch**

*Fits proportional hazards regression model to case-cohort data*

**Description**

Returns estimates and standard errors from relative risk regression fit to data from case-cohort studies. A choice is available among the Prentice, Self-Prentice and Lin-Ying methods for unstratified data. For stratified data the choice is between Borgan I, a generalization of the Self-Prentice estimator for unstratified case-cohort data, and Borgan II, a generalization of the Lin-Ying estimator.

**Usage**

```
cch(formula, data = sys.parent(), subcoh, id, stratum=NULL, cohort.size,
 method =c("Prentice","SelfPrentice","LinYing","I.Borgan","II.Borgan"),
 robust=FALSE)
```

**Arguments**

|             |                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula     | A formula object that must have a <a href="#">Surv</a> object as the response. The Surv object must be of type "right", or of type "counting".                                                            |
| subcoh      | Vector of indicators for subjects sampled as part of the sub-cohort. Code 1 or TRUE for members of the sub-cohort, 0 or FALSE for others. If data is a data frame then subcoh may be a one-sided formula. |
| id          | Vector of unique identifiers, or formula specifying such a vector.                                                                                                                                        |
| stratum     | A vector of stratum indicators or a formula specifying such a vector                                                                                                                                      |
| cohort.size | Vector with size of each stratum original cohort from which subcohort was sampled                                                                                                                         |
| data        | An optional data frame in which to interpret the variables occurring in the formula.                                                                                                                      |
| method      | Three procedures are available. The default method is "Prentice", with options for "SelfPrentice" or "LinYing".                                                                                           |
| robust      | For "LinYing" only, if robust=TRUE, use design-based standard errors even for phase I                                                                                                                     |

## Details

Implements methods for case-cohort data analysis described by Therneau and Li (1999). The three methods differ in the choice of "risk sets" used to compare the covariate values of the failure with those of others at risk at the time of failure. "Prentice" uses the sub-cohort members "at risk" plus the failure if that occurs outside the sub-cohort and is score unbiased. "SelfPren" (Self-Prentice) uses just the sub-cohort members "at risk". These two have the same asymptotic variance-covariance matrix. "LinYing" (Lin-Ying) uses the all members of the sub-cohort and all failures outside the sub-cohort who are "at risk". The methods also differ in the weights given to different score contributions.

The `data` argument must not have missing values for any variables in the model. There must not be any censored observations outside the subcohort.

## Value

An object of class "cch" incorporating a list of estimated regression coefficients and two estimates of their asymptotic variance-covariance matrix.

|                        |                                                       |
|------------------------|-------------------------------------------------------|
| <code>coef</code>      | regression coefficients.                              |
| <code>naive.var</code> | Self-Prentice model based variance-covariance matrix. |
| <code>var</code>       | Lin-Ying empirical variance-covariance matrix.        |

cgd

*Chronic Granulomatous Disease data*

### Description

Data are from a placebo controlled trial of gamma interferon in chronic granulomatous disease (CGD). Uses the complete data on time to first serious infection observed through end of study for each patient, which includes the initial serious infections observed through the 7/15/89 interim analysis data cutoff, plus the residual data on occurrence of initial serious infections between the interim analysis cutoff and the final blinded study visit for each patient. Only one patient was taken off on the day of his last infection.

### Usage

cgd

**clogit**

*Conditional logistic regression*

---

## Description

Estimates a logistic regression model by maximising the conditional likelihood. Uses a model formula of the form `case.status~exposure+strata(matched.set)`. The default is to use the exact conditional likelihood, a commonly used approximate conditional likelihood is provided for compatibility with older software.

## Usage

```
clogit(formula, data, weights, subset, na.action,
method=c("exact", "approximate", "efron", "breslow"),
...)
```

## Arguments

|                        |                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------|
| <code>formula</code>   | Model formula                                                                                          |
| <code>data</code>      | data frame                                                                                             |
| <code>weights</code>   | optional, names the variable containing case weights                                                   |
| <code>subset</code>    | optional, subset the data                                                                              |
| <code>na.action</code> | optional <code>na.action</code> argument. By default the global option <code>na.action</code> is used. |
| <code>method</code>    | use the correct (exact) calculation in the conditional likelihood or one of the approximations         |
| <code>...</code>       | optional arguments, which will be passed to <code>coxph.control</code>                                 |

## Details

It turns out that the logliklihood for a conditional logistic regression model = loglik from a Cox model with a particular data structure. Proving this is a nice homework exercise for a PhD statistics class; not too hard, but the fact that it is true is surprising.

When a well tested Cox model routine is available many packages use this ‘trick’ rather than writing a new software routine from scratch, and this is what the clogit routine does. In detail, a stratified Cox model with each case/control group assigned to its own stratum, time set to a constant, status of 1=case 0=control, and using the exact partial likelihood has the same likelihood formula as a conditional logistic regression. The clogit routine creates the necessary dummy variable of times (all 1) and the strata, then calls coxph.

The computation of the exact partial likelihood can be very slow, however. If a particular strata had say 10 events out of 20 subjects we have to add up a denominator that involves all possible ways of choosing 10 out of 20, which is  $20!/(10! \cdot 10!) = 184756$  terms. Gail et al describe a fast recursion method which largely ameleeorates this; it was incorporated into version 2.36-11 of the survival package. Most of the time conditional logistic modeling is applied data with 1 case + k controls per set, however, where the above the computational issue above does not arise. Thus most users will not notice the change but for others computation time will drop precipitously. The ‘appoximate’ option maps to the Breslow approximation for the Cox model, for historical reasons.

It is not clear how case weights should be handled. For instance if there are two deaths in a strata, one with weight=1 and one with weight=2, should the likelihood calculation consider all subsets of size 2 or all subsets of size 3? Consequently, case weights are ignored by the routine.

## Value

An object of class "clogit", which is a wrapper for a "coxph" object.

## Examples

```
Not run: clogit(case ~ spontaneous + induced + strata(stratum), data=infert)

A multinomial response recoded to use clogit
The revised data set has one copy per possible outcome level, with new
variable tocc = target occupation for this copy, and case = whether
that is the actual outcome for each subject.
See the catspec package for more details on the Logan approach.
resp <- levels(logan$occupation)
n <- nrow(logan)
indx <- rep(1:n, length(resp))
logan2 <- data.frame(logan[indx,],
 id = indx,
```

---

```

tocc = factor(rep(resp, each=n)))
logan2$case <- (logan2$occupation == logan2$tocc)
clogit(case ~ tocc + tocc:education + strata(id), logan2)

```

---

**cluster***Identify clusters.***Description**

This is a special function used in the context of survival models. It identifies correlated groups of observations, and is used on the right hand side of a formula. Using `cluster()` in a formula implies that robust sandwich variance estimators are desired.

**Usage**

```
cluster(x)
```

**Arguments**

|                |                                           |
|----------------|-------------------------------------------|
| <code>x</code> | A character, factor, or numeric variable. |
|----------------|-------------------------------------------|

**Details**

The function's only action is semantic, to mark a variable as the cluster indicator. The resulting variance is what is known as the “working independence” variance in a GEE model. Note that one cannot use both a frailty term and a cluster term in the same model, the first is a mixed-effects approach to correlation and the second a GEE approach, and these don't mix.

**Value**

```
x
```

**See Also**

**colon***Chemotherapy for Stage B/C colon cancer*

---

**Description**

These are data from one of the first successful trials of adjuvant chemotherapy for colon cancer. Levamisole is a low-toxicity compound previously used to treat worm infestations in animals; 5-FU is a moderately toxic (as these things go) chemotherapy agent. There are two records per person, one for recurrence and one for death

**Usage**

colon

**Format**

|           |                                                                                   |

| node4:    | more than 4 positive lymph nodes                                                  |
| etype:    | event type: 1=recurrence,2=death                                                  |

**Note**

The study is originally described in Laurie (1989). The main report is found in Moertel (1990). This data set is closest to that of the final report in Moertel (1991). A version of the data with less follow-up time was used in the paper by Lin (1994).

cox.zph

*Test the Proportional Hazards Assumption of a Cox Regression*

## Description

Test the proportional hazards assumption for a Cox regression model fit (coxph).

## Usage

```
cox.zph(fit, transform="km", global=TRUE)
```

## Arguments

- |           |                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| fit       | the result of fitting a Cox regression model, using the coxph function.                                                                                                              |
| transform | a character string specifying how the survival times should be transformed before the test is performed. Possible values are "km", "rank", "identity" or a function of one argument. |
| global    | should a global chi-square test be done, in addition to the per-variable tests.                                                                                                      |

## Value

an object of class "cox.zph", with components:

- |       |                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| table | a matrix with one row for each variable, and optionally a last row for the global test. Columns of the matrix contain the correlation coefficient between transformed survival time and the scaled Schoenfeld residuals, a chi-square, and the two-sided p-value. For the global test there is no appropriate correlation, so an NA is entered into the matrix as a placeholder.                                                                          |
| x     | the transformed time axis.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| y     | the matrix of scaled Schoenfeld residuals. There will be one column per variable and one row per event. The row labels contain the original event times (for the identity transform, these will be the same as x).                                                                                                                                                                                                                                        |
| call  | the calling sequence for the routine.<br>The computations require the original x matrix of the Cox model fit. Thus it saves time if the x=TRUE option is used in coxph. This function would usually be followed by both a plot and a print of the result. The plot gives an estimate of the time-dependent coefficient beta(t). If the proportional hazards assumption is true, beta(t) will be a horizontal line. The printout gives a test for slope=0. |

**coxph**

*Fit Proportional Hazards Regression Model*

**Description**

Fits a Cox proportional hazards regression model. Time dependent variables, time dependent strata, multiple events per subject, and other extensions are incorporated using the counting process formulation of Andersen and Gill.

**Usage**

```
coxph(formula, data=, weights, subset,
 na.action, init, control,
 ties=c("efron","breslow","exact"),
 singular.ok=TRUE, robust=FALSE,
 model=FALSE, x=FALSE, y=TRUE, tt, method, ...)
```

**Arguments**

|                  |                                                                                                                                                                                                                                                     |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>formula</b>   | a formula object, with the response on the left of a <code>~</code> operator, and the terms on the right. The response must be a survival object as returned by the <code>Surv</code> function.                                                     |
| <b>data</b>      | a <code>data.frame</code> in which to interpret the variables named in the <code>formula</code> , or in the <code>subset</code> and the <code>weights</code> argument.                                                                              |
| <b>weights</b>   | vector of case weights. If <code>weights</code> is a vector of integers, then the estimated coefficients are equivalent to estimating the model from data with the individual cases replicated as many times as indicated by <code>weights</code> . |
| <b>subset</b>    | expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.                                                                                                                         |
| <b>na.action</b> | a missing-data filter function. This is applied to the <code>model.frame</code> after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .                                                                |
| <b>init</b>      | vector of initial values of the iteration. Default initial value is zero for all variables.                                                                                                                                                         |
| <b>control</b>   | Object of class <code>coxph.control</code> specifying iteration limit and other control options. Default is <code>coxph.control(...)</code> .                                                                                                       |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ties</b>        | a character string specifying the method for tie handling. If there are no tied death times all the methods are equivalent. Nearly all Cox regression programs use the Breslow method by default, but not this one. The Efron approximation is used as the default here, it is more accurate when dealing with tied death times, and is as efficient computationally. The “exact partial likelihood” is equivalent to a conditional logistic model, and is appropriate when the times are a small set of discrete values. If there are a large number of ties and (start, stop) style survival data the computational time will be excessive. |
| <b>singular.ok</b> | logical value indicating how to handle collinearity in the model matrix. If TRUE, the program will automatically skip over columns of the X matrix that are linear combinations of earlier columns. In this case the coefficients for such columns will be NA, and the variance matrix will contain zeros. For ancillary calculations, such as the linear predictor, the missing coefficients are treated as zeros.                                                                                                                                                                                                                           |
| <b>robust</b>      | this argument has been deprecated, use a cluster term in the model instead.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>model</b>       | logical value: if TRUE, the model frame is returned in component <b>model</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>x</b>           | logical value: if TRUE, the x matrix is returned in component <b>x</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>y</b>           | logical value: if TRUE, the response vector is returned in component <b>y</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>tt</b>          | optional list of time-transform functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>method</b>      | alternate name for the <b>ties</b> argument.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>...</b>         | Other arguments will be passed to <a href="#">coxph.control</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Details

The proportional hazards model is usually expressed in terms of a single survival time value for each person, with possible censoring. Andersen and Gill reformulated the same problem as a counting process; as time marches onward we observe the events for a subject, rather like watching a Geiger counter. The data for a subject is presented as multiple rows or "observations", each of which applies to an interval of observation (start, stop].

The routine internally scales and centers data to avoid overflow in the argument to the exponential function. These actions do not change the result, but lead to more numerical stability. However, arguments to offset are not scaled since there are situations where a large offset value is a purposefully used. Users should not use normally allow large numeric offset values.

## Value

an object of class **coxph** representing the fit. See **coxph.object** for details.

## Side Effects

Depending on the call, the **predict**, **residuals**, and **survfit** routines may need to reconstruct the **x** matrix created by **coxph**. It is possible for this to fail, as in the example below in which the **predict** function is unable to find **tform**.

```
tfun <- function(tform) coxph(tform, data=lung)
fit <- tfun(Surv(time, status) ~ age)
predict(fit)
```

In such a case add the **model=TRUE** option to the **coxph** call to obviate the need for reconstruction, at the expense of a larger **fit** object.

## Special terms

There are three special terms that may be used in the model equation. A `strata` term identifies a stratified Cox model; separate baseline hazard functions are fit for each strata. The `cluster` term is used to compute a robust variance for the model. The term `+ cluster(id)` where each value of `id` is unique is equivalent to specifying the `robust=T` argument, and produces an approximate jackknife estimate of the variance. If the `id` variable were not unique, but instead identifies clusters of correlated observations, then the variance estimate is based on a grouped jackknife.

A time-transform term allows variables to vary dynamically in time. In this case the `tt` argument will be a function or a list of functions (if there are more than one `tt()` term in the model) giving the appropriate transform. See the examples below.

## Convergence

In certain data cases the actual MLE estimate of a coefficient is infinity, e.g., a dichotomous variable where one of the groups has no events. When this happens the associated coefficient grows at a steady pace and a race condition will exist in the fitting routine: either the log likelihood converges, the information matrix becomes effectively singular, an argument to `exp` becomes too large for the computer hardware, or the maximum number of interactions is exceeded. (Nearly always the first occurs.) The routine attempts to detect when this has happened, not always successfully. The primary consequence for the user is that the Wald statistic = `coefficient/se(coefficient)` is not valid in this case and should be ignored; the likelihood ratio and score tests remain valid however.

## Penalized regression

`coxph` can now maximise a penalised partial likelihood with arbitrary user-defined penalty. Supplied penalty functions include ridge regression ([ridge](#)), smoothing splines ([pspline](#)), and frailty models ([frailty](#)).

## Examples

```
Create the simplest test data set
test1 <- list(time=c(4,3,1,1,2,2,3),
 status=c(1,1,1,0,1,1,0),
 x=c(0,2,1,1,1,0,0),
 sex=c(0,0,0,0,1,1,1))

Fit a stratified model
coxph(Surv(time, status) ~ x + strata(sex), test1)
Create a simple data set for a time-dependent model
test2 <- list(start=c(1,2,5,2,1,7,3,4,8,8),
 stop=c(2,3,6,7,8,9,9,9,14,17),
 event=c(1,1,1,1,1,1,0,0,0),
 x=c(1,0,0,1,0,1,1,0,0))
```

```

summary(coxph(Surv(start, stop, event) ~ x, test2))

#
Create a simple data set for a time-dependent model
#
test2 <- list(start=c(1, 2, 5, 2, 1, 7, 3, 4, 8, 8),
 stop =c(2, 3, 6, 7, 8, 9, 9, 9, 14,17),
 event=c(1, 1, 1, 1, 1, 1, 0, 0, 0),
 x =c(1, 0, 0, 1, 0, 1, 1, 1, 0, 0))

summary(coxph(Surv(start, stop, event) ~ x, test2))

Fit a stratified model, clustered on patients

bladder1 <- bladder[bladder$enum < 5,]
coxph(Surv(stop, event) ~ (rx + size + number) * strata(enum) +
 cluster(id), bladder1)

Fit a time transform model using current age
coxph(Surv(time, status) ~ ph.ecog + tt(age), data=lung,
 tt=function(x,t,...) pspline(x + t/365.25))

```

**coxph.control***Ancillary arguments for controlling coxph fits***Description**

This is used to set various numeric parameters controlling a Cox model fit. Typically it would only be used in a call to `coxph`.

**Usage**

```
coxph.control(eps = 1e-09, toler.chol = .Machine$double.eps^0.75,
iter.max = 20, toler.inf = sqrt(eps), outer.max = 10)
```

**Arguments**

|                         |                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>eps</code>        | Iteration continues until the relative change in the log partial likelihood is less than <code>eps</code> . Must be positive.                                                    |
| <code>toler.chol</code> | Tolerance for detection of singularity during a Cholesky decompositon of the variance matrix, i.e., for detecting a redundant predictor variable.                                |
| <code>iter.max</code>   | Maximum number of iterations to attempt for convergence.                                                                                                                         |
| <code>toler.inf</code>  | Tolerance criteria for the warning message about a possible infinite coefficient value.                                                                                          |
| <code>outer.max</code>  | For a penalized coxph model, e.g. with pspline terms, there is an outer loop of iteration to determine the penalty parameters; maximum number of iterations for this outer loop. |

**Value**

a list containing the values of each of the above constants

coxph.detail

*Details of a Cox Model Fit*

---

**Description**

Returns the individual contributions to the first and second derivative matrix, at each unique event time.

**Usage**

```
coxph.detail(object, riskmat=FALSE)
```

**Arguments**

- |         |                                                              |
|---------|--------------------------------------------------------------|
| object  | a Cox model object, i.e., the result of <code>coxph</code> . |
| riskmat | include the at-risk indicator matrix in the output?          |

**Details**

This function may be useful for those who wish to investigate new methods or extensions to the Cox model. The example below shows one way to calculate the Schoenfeld residuals.

**Value**

a list with components

- |        |                                                                                                                                                                                                                                                                   |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| time   | the vector of unique event times                                                                                                                                                                                                                                  |
| nevent | the number of events at each of these time points.                                                                                                                                                                                                                |
| means  | a matrix with one row for each event time and one column for each variable in the Cox model, containing the weighted mean of the variable at that time, over all subjects still at risk at that time. The weights are the risk weights $\exp(x \%*\% fit$coef)$ . |
| nrisk  | number of subjects at risk.                                                                                                                                                                                                                                       |
| score  | the contribution to the score vector (first derivative of the log partial likelihood) at each time point.                                                                                                                                                         |
| imat   | the contribution to the information matrix (second derivative of the log partial likelihood) at each time point.                                                                                                                                                  |
| hazard | the hazard increment. Note that the hazard and variance of the hazard are always for some particular future subject. This routine uses <code>object\$mean</code> as the future subject.                                                                           |
| varhaz | the variance of the hazard increment.                                                                                                                                                                                                                             |
| x,y    | copies of the input data.                                                                                                                                                                                                                                         |

|                |                                                                                                                                                                                             |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>strata</b>  | only present for a stratified Cox model, this is a table giving the number of time points of component time that were contributed by each of the strata.                                    |
| <b>riskmat</b> | a matrix with one row for each time and one column for each observation containing a 0/1 value to indicate whether that observation was (1) or was not (0) at risk at the given time point. |

## See Also

## Examples

```
fit <- coxph(Surv(futime,fustat) ~ age + rx + ecog.ps, ovarian, x=TRUE)
fitd <- coxph.detail(fit)
There is one Schoenfeld residual for each unique death. It is a
vector (covariates for the subject who died) - (weighted mean covariate
vector at that time). The weighted mean is defined over the subjects
still at risk, with exp(X beta) as the weight.

events <- fit$y[,2]==1
etime <- fit$y[events,1] #the event times --- may have duplicates
indx <- match(etime, fitd$time)
schoen <- fit$x[events,] - fitd$means[indx,]
```

## Description

This class of objects is returned by the `coxph` class of functions to represent a fitted proportional hazards model. Objects of this class have methods for the functions `print`, `summary`, `residuals`, `predict` and `survfit`.

## Arguments

|                     |                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>coefficients</b> | the vector of coefficients. If the model is over-determined there will be missing values in the vector corresponding to the redundant columns in the model matrix.                                                         |
| <b>var</b>          | the variance matrix of the coefficients. Rows and columns corresponding to any missing coefficients are set to zero.                                                                                                       |
| <b>naive.var</b>    | this component will be present only if the <code>robust</code> option was true. If so, the <code>var</code> component will contain the robust estimate of variance, and this component will contain the ordinary estimate. |
| <b>loglik</b>       | a vector of length 2 containing the log-likelihood with the initial values and with the final values of the coefficients.                                                                                                  |
| <b>score</b>        | value of the efficient score test, at the initial value of the coefficients.                                                                                                                                               |
| <b>rscore</b>       | the robust log-rank statistic, if a robust variance was requested.                                                                                                                                                         |
| <b>wald.test</b>    | the Wald test of whether the final coefficients differ from the initial values.                                                                                                                                            |
| <b>iter</b>         | number of iterations used.                                                                                                                                                                                                 |

|                          |                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>linear.predictors</b> | the vector of linear predictors, one per subject. Note that this vector has been centered, see <code>predict.coxph</code> for more details.                                                                                                                                                                                                                                  |
| <b>residuals</b>         | the martingale residuals.                                                                                                                                                                                                                                                                                                                                                    |
| <b>means</b>             | vector of column means of the X matrix. Subsequent survival curves are adjusted to this value.                                                                                                                                                                                                                                                                               |
| <b>n</b>                 | the number of observations used in the fit.                                                                                                                                                                                                                                                                                                                                  |
| <b>nevent</b>            | the number of events (usually deaths) used in the fit.                                                                                                                                                                                                                                                                                                                       |
| <b>weights</b>           | the vector of case weights, if one was used.                                                                                                                                                                                                                                                                                                                                 |
| <b>method</b>            | the computation method used.                                                                                                                                                                                                                                                                                                                                                 |
| <b>na.action</b>         | the <code>na.action</code> attribute, if any, that was returned by the <code>na.action</code> routine.<br>The object will also contain the following, for documentation see the <code>lm</code> object: <code>terms</code> , <code>assign</code> , <code>formula</code> , <code>call</code> , and, optionally, <code>x</code> , <code>y</code> , and/or <code>frame</code> . |

## Components

The following components must be included in a legitimate `coxph` object.

## See Also

[coxph](#), [coxph.detail](#), [cox.zph](#), [residuals.coxph](#), [survfit](#), [survreg](#).

**dsurvreg**

*Distributions available in survreg.*

## Description

Density, cumulative probability, and quantiles for the set of distributions supported by the `survreg` function.

## Usage

```
dsurvreg(x, mean, scale=1, distribution='weibull', parms)
psurvreg(q, mean, scale=1, distribution='weibull', parms)
qsurvreg(p, mean, scale=1, distribution='weibull', parms)
```

## Arguments

|                     |                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>            | vector of quantiles. Missing values (NAs) are allowed.                                                                       |
| <b>q</b>            | vector of quantiles. Missing values (NAs) are allowed.                                                                       |
| <b>p</b>            | vector of probabilities. Missing values (NAs) are allowed.                                                                   |
| <b>mean</b>         | vector of means. This is replicated to be the same length as <b>p</b> or <b>q</b> .                                          |
| <b>scale</b>        | vector of (positive) scale factors. This is replicated to be the same length as <b>p</b> or <b>q</b> .                       |
| <b>distribution</b> | character string giving the name of the distribution. This must be one of the elements of <code>survreg.distributions</code> |
| <b>parms</b>        | optional parameters, if any, of the distribution. For the t-distribution this is the degrees of freedom.                     |

## Details

Elements of q or p that are missing will cause the corresponding elements of the result to be missing.

The mean and scale values are as they would be for survreg. In particular, if the distribution is one that involves a transformation, then they are the mean and scale of the transformed distribution. For example, the Weibull distribution is fit using the Extreme value distribution along with a log transformation. Letting  $F(t) = 1 - \exp[-(at)^p]$  be the cumulative distribution of the Weibull, the mean corresponds to  $-\log(a)$  and the scale to  $1/p$  (Kalbfleish and Prentice, section 2.2.2).

## Value

density (dsurvreg), probability (psurvreg), quantile (qsurvreg), or for the requested distribution with mean and scale parameters mean and sd.

Hazard function for a Weibull distribution
x <- seq(.1, 3, length=30)
haz <- dsurvreg(x, 2, 3)/(1-psurvreg(x, 2, 3))
Not run:
plot(x, haz, log='xy', ylab="Hazard") #line with slope (1/scale -1)

End(Not run)
```

## Description

The frailty function allows one to add a simple random effects term to a Cox or survreg model.

## Usage

```
frailty(x, distribution="gamma", ...)
frailty.gamma(x, sparse = (nclass > 5), theta, df, eps = 1e-05, method = c("em","aic", "df", "fixed")
frailty.gaussian(x, sparse = (nclass > 5), theta, df, method =c("reml","aic", "df", "fixed"), ...
frailty.t(x, sparse = (nclass > 5), theta, df, eps = 1e-05, tdf = 5,method = c("aic", "df", "fixed"))
```

## Arguments

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>            | the variable to be entered as a random effect. It is always treated as a factor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>distribution</code> | either the gamma, gaussian or t distribution may be specified. The routines <code>frailty.gamma</code> , <code>frailty.gaussian</code> and <code>frailty.t</code> do the actual work.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>...</code>          | Arguments for specific distribution, including (but not limited to)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>sparse</code>       | cutoff for using a sparse coding of the data matrix. If the total number of levels of <code>x</code> is larger than this value, then a sparse matrix approximation is used. The correct cutoff is still a matter of exploration: if the number of levels is very large (thousands) then the non-sparse calculation may not be feasible in terms of both memory and compute time. Likewise, the accuracy of the sparse approximation appears to be related to the maximum proportion of subjects in any one class, being best when no one class has a large membership.                                       |
| <code>theta</code>        | if specified, this fixes the variance of the random effect. If not, the variance is a parameter, and a best solution is sought. Specifying this implies <code>method='fixed'</code> .                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>df</code>           | if specified, this fixes the degrees of freedom for the random effect. Specifying this implies <code>method='df'</code> . Only one of <code>theta</code> or <code>df</code> should be specified.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>method</code>       | the method used to select a solution for theta, the variance of the random effect. The <code>fixed</code> corresponds to a user-specified value, and no iteration is done. The <code>df</code> selects the variance such that the degrees of freedom for the random effect matches a user specified value. The <code>aic</code> method seeks to maximize Akaike's information criteria $2*(\text{partial likelihood} - \text{df})$ . The <code>em</code> and <code>reml</code> methods are specific to Cox models with gamma and gaussian random effects, respectively. Please see further discussion below. |
| <code>tdf</code>          | the degrees of freedom for the t-distribution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>eps</code>          | convergence criteria for the iteration on theta.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Details

The `frailty` plugs into the general penalized modeling framework provided by the `coxph` and `survreg` routines. This framework deals with likelihood, penalties, and degrees of freedom; these aspects work well with either parent routine.

Therneau, Grambsch, and Pankratz show how maximum likelihood estimation for the Cox model with a gamma frailty can be accomplished using a general penalized routine, and Ripatti and Palmgren work through a similar argument for the Cox model with a gaussian frailty. Both of these are specific to the Cox model. Use of `gamma/ml` or `gaussian/reml` with `survreg` does not lead to valid results.

The extensible structure of the penalized methods is such that the penalty function, such as `frailty` or `pspline`, is completely separate from the modeling routine. The strength of this is that a user can plug in any penalization routine they choose. A weakness is that it is very difficult for the modeling routine to know whether a sensible penalty routine has been supplied.

Note that use of a frailty term implies a mixed effects model and use of a cluster term implies a GEE approach; these cannot be mixed.

The `coxme` package has superseded this method. It is faster, more stable, and more flexible.

### **Value**

this function is used in the model statement of either `coxph` or `survreg`. Its results are used internally.

**is.ratetable**

Verify that an object is of class *ratetable*.

## Description

The function verifies not only the `class` attribute, but the structure of the object.

## Usage

```
is.ratetable(x, verbose=FALSE)
```

## Arguments

- x the object to be verified.
- verbose if TRUE and the object is not a ratetable, then return a character string describing the way(s) in which x fails to be a proper ratetable object.

## Details

Rate tables are used by the `pyears` and `survexp` functions, and normally contain death rates for some population, categorized by age, sex, or other variables. They have a fairly rigid structure, and the `verbose` option can help in creating a new rate table.

## Value

returns TRUE if `x` is a ratetable, and FALSE or a description if it is not.

## See Also

[pyears](#), [survexp](#).

## Examples

```
is.ratetable(survexp.us) # True
is.ratetable(cancer) # False
```

`kidney`

*Kidney catheter data*

## Description

Data on the recurrence times to infection, at the point of insertion of the catheter, for kidney patients using portable dialysis equipment. Catheters may be removed for reasons other than infection, in which case the observation is censored. Each patient has exactly 2 observations.

This data has often been used to illustrate the use of random effects (frailty) in a survival model. However, one of the males (id 21) is a large outlier, with much longer survival than his peers. If this observation is removed no evidence remains for a random subject effect.

## Format

|          |                                           |
|----------|-------------------------------------------|
| patient: | <code>id</code>                           |
| time:    | <code>time</code>                         |
| status:  | <code>event status</code>                 |
| age:     | in years                                  |
| sex:     | 1=male, 2=female                          |
| disease: | disease type (0=GN, 1=AN, 2=PKD, 3=Other) |
| frail:   | frailty estimate from original paper      |

## Note

The original paper ignored the issue of tied times and so is not exactly reproduced by the survival package.

## Source

CA McGilchrist, CW Aisbett (1991), Regression with frailty in survival analysis. *Biometrics* **47**, 461–66.

## Examples

```
kfit <- coxph(Surv(time, status)~ age + sex + disease + frailty(id), kidney)
kfit0 <- coxph(Surv(time, status)~ age + sex + disease, kidney)
kfitm1 <- coxph(Surv(time,status) ~ age + sex + disease +
frailty(id, dist='gauss'), kidney)
```

|                            |                                               |
|----------------------------|-----------------------------------------------|
| <code>lines.survfit</code> | <i>Add Lines or Points to a Survival Plot</i> |
|----------------------------|-----------------------------------------------|

## Description

Often used to add the expected survival curve(s) to a Kaplan-Meier plot generated with `plot.survfit`.

## Usage

```
S3 method for class 'survfit'
lines(x, type="s", mark=3, col=1, lty=1,
lwd=1, mark.time=TRUE,
xscale=1, firstx=0, firsty=1, xmax, fun, conf.int=FALSE, ...)
S3 method for class 'survexp'
points(x, xscale, xmax, fun, ...)
```

## Arguments

- `x` a survival object, generated from the `survfit` or `survexp` functions.
- `type` the line type, as described in `lines`. The default is a step function for `survfit` objects, and a connected line for `survexp` objects.
- `mark, col, lty, lwd` vectors giving the mark symbol, color, line type and line width for the added curves.
- `...` other graphical parameters
- `mark.time` controls the labeling of the curves. If `FALSE`, no labeling is done. If `TRUE`, then curves are marked at each censoring time. If `mark.time` is a numeric vector, then curves are marked at the specified time points.
- `xscale` a number used to divide the x values. If time was originally in days, a value of 365.25 would give a plotted scale in years.
- `firstx, firsty` the starting point for the survival curves. If either of these is set to `NA` or <blank> the plot will start at the first time point of the curve.
- `xmax` the maximum horizontal plot coordinate. This shortens the curve before plotting it, so unlike using the `xlim` graphical parameter, warning messages about out of bounds points are not generated.

- fun** an arbitrary function defining a transformation of the survival curve. For example `fun=log` is an alternative way to draw a log-survival curve (but with the axis labeled with  $\log(S)$  values). Four often used transformations can be specified with a character argument instead: "log" is the same as using the `log=T` option, "event" plots cumulative events ( $f(y) = 1-y$ ), "cumhaz" plots the cumulative hazard function ( $f(y) = -\log(y)$ ) and "cloglog" creates a complimentary log-log survival plot ( $f(y) = \log(-\log(y))$  along with log scale for the x-axis).
- conf.int** if `TRUE`, confidence bands for the curves are also plotted. If set to "only", then only the CI bands are plotted, and the curve itself is left off. This can be useful for fine control over the colors or line types of a plot.

## Details

When the `survfit` function creates a multi-state survival curve the resulting object has class 'survfm'. The only difference in the plots is that that it defaults to a curve that goes from lower left to upper right (starting at 0), where survival curves default to starting at 1 and going down. All other options are identical.

## Value

a list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not of the confidence limits). This may be useful for labeling.

## Side Effects

one or more curves are added to the current plot.

## See Also

`logan`

*Data from the 1972-78 GSS data used by Logan*

---

### Description

Intergenerational occupational mobility data with covariates.

### Usage

```
data(logan)
```

### Format

A data frame with 838 observations on the following 4 variables.

**occupation** subject's occupation, a factor with levels farm, operatives, craftsmen, sales, and professional

**focc** father's occupation

**education** total years of schooling, 0 to 20

**race** levels of non-black and black

### Source

mgus

*Monoclonal gammopathy data*

**Description**

Natural history of 241 subjects with monoclonal gammopathy of undetermined significance (MGUS).

**Usage**

mgus  
mgus1  
mgus2

**Format**

mgus: A data frame with 241 observations on the following 12 variables.

|       |                                                                                                                  |
|-------|------------------------------------------------------------------------------------------------------------------|
| id:   | subject id                                                                                                       |
| age:  | age in years                                                                                                     |
| sex:  | male or female                                                                                                   |
| dxyr: | year of diagnosis                                                                                                |
| pcdx: | for subjects who progress to a plasma cell malignancy<br>the subtype of malignancy: multiple myeloma (MM) is the |

most common, followed by amyloidosis (AM), macroglobulinemia (MA), and other lymphoproliferative (LP)

pctime: days from MGUS until diagnosis of a plasma cell malignancy  
futime: days from diagnosis to last follow-up  
death: 1= follow-up is until death  
alb: albumin level at MGUS diagnosis  
creat: creatinine at MGUS diagnosis  
hgb: hemoglobin at MGUS diagnosis  
mspike: size of the monoclonal protein spike at diagnosis

mgus1: The same data set in start,stop format. Contains the id, age, sex, and laboratory variable described above along with

start, stop: sequential intervals of time for each subject  
status: =1 if the interval ends in an event  
event: the event type

mgus2: The mgus data, but formatted in the competing risks style. Each subject has three observations, one for time to death, one for time to MM, and one for time to a PC malignancy other than MM. Contains the id, age, sex, and laboratory variable described above along with

time: time to event or censoring  
status: 1 if the event occurred, 0 otherwise  
event: death, myeloma, or other

## Details

Plasma cells are responsible for manufacturing immunoglobulins, an important part of the immune defense. At any given time there are estimated to be about  $10^6$  different immunoglobulins in the circulation at any one time. When a patient has a plasma cell malignancy the distribution will become dominated by a single isotype, the product of the malignant clone, visible as a spike on a serum protein electrophoresis. Monoclonal gammopathy of undetermined significance (MGUS) is the presence of such a spike, but in a patient with no evidence of overt malignancy. This data set of 241 sequential subjects at Mayo Clinic was the groundbreaking study defining the natural history of such subjects.

**model.frame.coxph**      *Model.frame method for coxph objects*

## Description

Recreate the model frame of a coxph fit.

## Usage

```
S3 method for class 'coxph'
model.frame(formula, ...)
```

## Arguments

|         |                                             |
|---------|---------------------------------------------|
| formula | the result of a coxph fit                   |
| ...     | other arguments to <code>model.frame</code> |

## Details

For details, see the manual page for the generic function. This function would rarely be called by a user, it is mostly used inside functions like `residual` that need to recreate the data set from a model in order to do further calculations.

## Value

the model frame used in the original fit, or a parallel one for new data.

## Author(s)

Terry Therneau

## See Also

[model.frame](#)

**model.matrix.coxph**      *Model.matrix method for coxph models*

## Description

Reconstruct the model matrix for a cox model.

## Usage

```
S3 method for class 'coxph'
model.matrix(object, data=NULL, contrast.arg =
object$contrasts, ...)
```

### Arguments

|              |                                                                     |
|--------------|---------------------------------------------------------------------|
| object       | the result of a coxph model                                         |
| data         | optional, a data frame from which to obtain the data                |
| contrast.arg | optional, a contrasts object describing how factors should be coded |
| ...          | other possible argument to model.frame                              |

### Details

When there is a data argument this function differs from most of the other `model.matrix` methods in that the response variable for the original formula is *not* required to be in the data.

If the data frame contains a `terms` attribute then it is assumed to be the result of a call to `model.frame`, otherwise a call to `model.frame` is applied with the data as an argument.

### Value

The model matrix for the fit

### Author(s)

Terry Therneau

### See Also

[model.matrix](#)

### Examples

```
fit1 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung)
xfit <- model.matrix(fit1)

fit2 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung,
 x=TRUE)
all.equal(model.matrix(fit1), fit2$x)
```

### Description

Missing data/measurement error example. Tumor histology predicts survival, but prediction is stronger with central lab histology than with the local institution determination.

### Usage

nwtco

**Format**

A data frame with 4028 observations on the following 9 variables.

```
seqno id number
instit Histology from local institution
histol Histology from central lab
stage Disease stage
study study
rel indicator for relapse
edrel time to relapse
age age in months
in.subcohort Included in the subcohort for the example in the paper
```

pbc

*Mayo Clinic Primary Biliary Cirrhosis Data*

---

**Description**

This data is from the Mayo Clinic trial in primary biliary cirrhosis (PBC) of the liver conducted between 1974 and 1984. A total of 424 PBC patients, referred to Mayo Clinic during that ten-year interval, met eligibility criteria for the randomized placebo controlled trial of the drug D-penicillamine. The first 312 cases in the data set participated in the randomized trial and contain largely complete data. The additional 112 cases did not participate in the clinical trial, but consented to have basic measurements recorded and to be followed for survival. Six of those cases were lost to follow-up shortly after diagnosis, so the data here are on an additional 106 cases as well as the 312 randomized participants.

A nearly identical data set found in appendix D of Fleming and Harrington; this version has fewer missing values.

**Usage**

pbc

**Format**

|           |                                                                                       |

## Description

This data is a continuation of the PBC data set, and contains the follow-up laboratory data for each study patient. An analysis based on the data can be found in Murtagh, et. al.

The primary PBC data set contains only baseline measurements of the laboratory paramters. This data set contains multiple laboratory results, but only on the 312 randomized patients. Some base-line data values in this file differ from the original PBC file, for instance, the data errors in prothrombin time and age which were discovered after the original analysis (see Fleming and Harrington, figure 4.6.7).

One "feature" of the data deserves special comment. The last observation before death or liver transplant often has many more missing covariates than other data rows. The original clinical protocol for these patients specified visits at 6 months, 1 year, and annually thereafter. At these protocol visits lab values were obtained for a large pre-specified battery of tests. "Extra" visits, often undertaken because of worsening medical condition, did not necessarily have all this lab work. The missing values are thus potentially informative.

**plot.aareg**

*Plot an aareg object.*

## Description

Plot the estimated coefficient function(s) from a fit of Aalen's additive regression model.

## Usage

```
S3 method for class 'aareg'
plot(x, se=TRUE, maxtime, type='s', ...)
```

## Arguments

|         |                                                                      |
|---------|----------------------------------------------------------------------|
| x       | the result of a call to the aareg function                           |
| se      | if TRUE, standard error bands are included on the plot               |
| maxtime | upper limit for the x-axis.                                          |
| type    | graphical parameter for the type of line, default is "steps".        |
| ...     | other graphical parameters such as line type, color, or axis labels. |

### Side Effects

A plot is produced on the current graphical device.

*Graphical Test of Proportional Hazards*

### Description

Displays a graph of the scaled Schoenfeld residuals, along with a smooth curve.

### Usage

```
S3 method for class 'cox.zph'
plot(x, resid=TRUE, se=TRUE, df=4, nsmo=40, var, ...)
```

### Arguments

|                    |                                                                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>     | result of the <code>cox.zph</code> function.                                                                                                                                                                                                                                                                                    |
| <code>resid</code> | a logical value, if TRUE the residuals are included on the plot, as well as the smooth fit.                                                                                                                                                                                                                                     |
| <code>se</code>    | a logical value, if TRUE, confidence bands at two standard errors will be added.                                                                                                                                                                                                                                                |
| <code>df</code>    | the degrees of freedom for the fitted natural spline, <code>df=2</code> leads to a linear fit.                                                                                                                                                                                                                                  |
| <code>nsmo</code>  | number of points used to plot the fitted spline.                                                                                                                                                                                                                                                                                |
| <code>var</code>   | the set of variables for which plots are desired. By default, plots are produced in turn for each variable of a model. Selection of a single variable allows other features to be added to the plot, e.g., a horizontal line at zero or a main title. This has been superseded by a subscripting method; see the example below. |
| <code>...</code>   | additional graphical arguments passed to the <code>plot</code> function.                                                                                                                                                                                                                                                        |

### Side Effects

a plot is produced on the current graphics device.

## Examples

```
vfit <- coxph(Surv(time,status) ~ trt + factor(celltype) +
 karno + age, data=veteran, x=TRUE)
temp <- cox.zph(vfit)
plot(temp, var=5) # Look at Karnofsky score, old way of doing plot
plot(temp[5]) # New way with subscripting
abline(0, 0, lty=3)
Add the linear fit as well
abline(lm(temp$y[,5] ~ temp$x)$coefficients, lty=4, col=3)
title(main="VA Lung Study")
```

### plot.survfit

*Plot method for survfit objects*

## Description

A plot of survival curves is produced, one curve for each strata. The `log=T` option does extra work to avoid `log(0)`, and to try to create a pleasing result. If there are zeros, they are plotted by default at 0.8 times the smallest non-zero value on the curve(s).

## Usage

```
S3 method for class 'survfit'
plot(x, conf.int=, mark.time=TRUE,
 mark=3, col=1, lty=1, lwd=1, cex=1, log=FALSE, xscale=1, yscale=1,
 firstx=0, firsty=1, xmax, ymin=0, fun,
 xlab="", ylab="", xaxs="S", ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                   |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>x</code>         | an object of class <code>survfit</code> , usually returned by the <code>survfit</code> function.                                                                                                                                                                                                  |
| <code>conf.int</code>  | determines whether confidence intervals will be plotted. The default is to do so if there is only 1 curve, i.e., no strata.                                                                                                                                                                       |
| <code>mark.time</code> | controls the labeling of the curves. If set to <code>FALSE</code> , no labeling is done. If <code>TRUE</code> , then curves are marked at each censoring time which is not also a death time. If <code>mark.time</code> is a numeric vector, then curves are marked at the specified time points. |
| <code>mark</code>      | vector of mark parameters, which will be used to label the curves. The <code>lines</code> help file contains examples of the possible marks. The vector is reused cyclically if it is shorter than the number of curves.                                                                          |
| <code>col</code>       | a vector of integers specifying colors for each curve. The default value is 1.                                                                                                                                                                                                                    |
| <code>lty</code>       | a vector of integers specifying line types for each curve. The default value is 1.                                                                                                                                                                                                                |
| <code>lwd</code>       | a vector of numeric values for line widths. The default value is 1.                                                                                                                                                                                                                               |
| <code>cex</code>       | a numeric value specifying the size of the marks. This is not treated as a vector; all marks have the same size.                                                                                                                                                                                  |
| <code>log</code>       | a logical value, if <code>TRUE</code> the y axis will be on a log scale. Alternately, one of the standard character strings "x", "y", or "xy" can be given to specific logarithmic horizontal and/or vertical axes.                                                                               |

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>yscale</code>                       | a numeric value used to multiply the labels on the y axis. A value of 100, for instance, would be used to give a percent scale. Only the labels are changed, not the actual plot coordinates, so that adding a curve with "lines(surv.exp(...))", say, will perform as it did without the <code>yscale</code> argument.                                                                                                                                                                                                                                                                                                                                                               |
| <code>xscale</code>                       | a numeric value used like <code>yscale</code> for labels on the x axis. A value of 365.25 will give labels in years instead of the original days.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>firstx</code> , <code>firsty</code> | the starting point for the survival curves. If either of these is set to NA the plot will start at the first time point of the curve. By default, the plot program obeys tradition by having the plot start at (0,0).<br>If <code>start.time</code> argument is used in <code>survfit</code> , <code>firstx</code> is set to that value.                                                                                                                                                                                                                                                                                                                                              |
| <code>xmax</code>                         | the maximum horizontal plot coordinate. This can be used to shrink the range of a plot. It shortens the curve before plotting it, so that unlike using the <code>xlim</code> graphical parameter, warning messages about out of bounds points are not generated.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>ymin</code>                         | lower boundary for y values. Survival curves are most often drawn in the range of 0-1, even if none of the curves approach zero. The parameter is ignored if the <code>fun</code> argument is present, or if it has been set to NA.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>fun</code>                          | an arbitrary function defining a transformation of the survival curve. For example <code>fun=log</code> is an alternative way to draw a log-survival curve (but with the axis labeled with $\log(S)$ values), and <code>fun=sqrt</code> would generate a curve on square root scale. Four often used transformations can be specified with a character argument instead: "log" is the same as using the <code>log=T</code> option, "event" plots cumulative events ( $f(y) = 1-y$ ), "cumhaz" plots the cumulative hazard function ( $f(y) = -\log(y)$ ), and "cloglog" creates a complimentary log-log survival plot ( $f(y) = \log(-\log(y))$ along with log scale for the x-axis). |
| <code>xlab</code>                         | label given to the x-axis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>ylab</code>                         | label given to the y-axis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>xaxs</code>                         | either "S" for a survival curve or a standard x axis style as listed in <code>par</code> . Survival curves are usually displayed with the curve touching the y-axis, but not touching the bounding box of the plot on the other 3 sides. Type "S" accomplishes this by manipulating the plot range and then using the "i" style internally.                                                                                                                                                                                                                                                                                                                                           |
| ...                                       | for future methods                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Details

When the `survfit` function creates a multi-state survival curve the resulting object also has class 'survfitsms'. The only difference in the plots is that that it defaults to a curve that goes from lower left to upper right (starting at 0), where survival curves default to starting at 1 and going down. All other options are identical.

## Value

a list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not the confidence limits). This may be useful for labeling.

## See Also

`par`, `survfit`, `lines.survfit`.

## Examples

```
leukemia.surv <- survfit(Surv(time, status) ~ x, data = aml)
plot(leukemia.surv, lty = 2:3)
legend(100, .9, c("Maintenance", "No Maintenance"), lty = 2:3)
title("Kaplan-Meier Curves\nfor AML Maintenance Study")
lsurv2 <- survfit(Surv(time, status) ~ x, aml, type='fleming')
plot(lsurv2, lty=2:3, fun="cumhaz",
xlab="Months", ylab="Cumulative Hazard")
```

predict.coxph

*Predictions for a Cox model*

## Description

Compute fitted values and regression terms for a model fitted by `coxph`

## Usage

```
S3 method for class 'coxph'
predict(object, newdata,
type=c("lp", "risk", "expected", "terms"),
se.fit=FALSE, na.action=na.pass, terms=names(object$assign), collapse,
reference=c("strata", "sample"), ...)
```

## Arguments

|                        |                                                                                                                                                                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>object</code>    | the results of a <code>coxph</code> fit.                                                                                                                                                                                                                                                                      |
| <code>newdata</code>   | Optional new data at which to do predictions. If absent predictions are for the data frame used in the original fit.                                                                                                                                                                                          |
| <code>type</code>      | the type of predicted value. Choices are the linear predictor ("lp"), the risk score $\exp(lp)$ ("risk"), the expected number of events given the covariates and follow-up time ("expected"), and the terms of the linear predictor ("terms").                                                                |
| <code>se.fit</code>    | if TRUE, pointwise standard errors are produced for the predictions.                                                                                                                                                                                                                                          |
| <code>na.action</code> | applies only when the <code>newdata</code> argument is present, and defines the missing value action for the new data. The default is to include all observations. When there is no <code>newdata</code> , then the behavior of missing is dictated by the <code>na.action</code> option of the original fit. |
| <code>terms</code>     | if <code>type="terms"</code> , this argument can be used to specify which terms should be included; the default is all.                                                                                                                                                                                       |
| <code>collapse</code>  | optional vector of subject identifiers. If specified, the output will contain one entry per subject rather than one entry per observation.                                                                                                                                                                    |
| <code>reference</code> | reference for centering predictions, see details below                                                                                                                                                                                                                                                        |
| <code>...</code>       | For future methods                                                                                                                                                                                                                                                                                            |

## Details

The Cox model is a *relative* risk model; predictions of type "linear predictor", "risk", and "terms" are all relative to the sample from which they came. By default, the reference value for each of these is the mean covariate within strata. The primary underlying reason is statistical: a Cox model only predicts relative risks between pairs of subjects within the same strata, and hence the addition of a constant to any covariate, either overall or only within a particular stratum, has no effect on the fitted results. Using the `reference="strata"` option causes this to be true for predictions as well.

When the results of `predict` are used in further calculations it may be desirable to use a fixed reference level. Use of `reference="sample"` will use the overall means, and agrees with the `linear.predictors` component of the `coxph` object (which uses the overall mean for backwards compatibility with older code). Predictions of type="terms" are almost invariably passed forward to further calculation, so for these we default to using the sample as the reference.

Predictions of type "expected" incorporate the baseline hazard and are thus absolute instead of relative; the `reference` option has no effect on these.

Models that contain a `frailty` term are a special case: due to the technical difficulty, when there is a `newdata` argument the predictions will always be for a random effect of zero.

## Value

a vector or matrix of predictions, or a list containing the predictions (element "fit") and their standard errors (element "se.fit") if the `se.fit` option is TRUE.

## See Also

[predict](#), [coxph](#), [termplot](#)

## Examples

```
options(na.action=na.exclude) # retain NA in predictions
fit <- coxph(Surv(time, status) ~ age + ph.ecog + strata(inst), lung)
#lung data set has status coded as 1/2
mresid <- (lung$status-1) - predict(fit, type='expected') #Martingale resid
predict(fit,type="lp")
predict(fit,type="expected")
predict(fit,type="risk",se.fit=TRUE)
predict(fit,type="terms",se.fit=TRUE)
```

**`predict.survreg`**      *Predicted Values for a 'survreg' Object*

## Description

Predicted values for a `survreg` object

## Usage

```
S3 method for class 'survreg'
predict(object, newdata,
type=c("response", "link", "lp", "linear", "terms", "quantile",
"uquantile"),
se.fit=FALSE, terms=NULL, p=c(0.1, 0.9), na.action=na.pass, ...)
```

### Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object    | result of a model fit using the <code>survreg</code> function.                                                                                                                                                                                                                                                                                                                                                       |
| newdata   | data for prediction. If absent predictions are for the subjects used in the original fit.                                                                                                                                                                                                                                                                                                                            |
| type      | the type of predicted value. This can be on the original scale of the data (response), the linear predictor ("linear", with "lp" as an allowed abbreviation), a predicted quantile on the original scale of the data ("quantile"), a quantile on the linear predictor scale ("uquantile"), or the matrix of terms for the linear predictor ("terms"). At this time "link" and linear predictor ("lp") are identical. |
| se.fit    | if TRUE, include the standard errors of the prediction in the result.                                                                                                                                                                                                                                                                                                                                                |
| terms     | subset of terms. The default for residual type "terms" is a matrix with one column for every term (excluding the intercept) in the model.                                                                                                                                                                                                                                                                            |
| p         | vector of percentiles. This is used only for quantile predictions.                                                                                                                                                                                                                                                                                                                                                   |
| na.action | applies only when the newdata argument is present, and defines the missing value action for the new data. The default is to include all observations.                                                                                                                                                                                                                                                                |
| ...       | for future methods                                                                                                                                                                                                                                                                                                                                                                                                   |

### Value

a vector or matrix of predicted values.

**print.aareg** *Print an aareg object*

## Description

Print out a fit of Aalen's additive regression model

## Usage

```
S3 method for class 'aareg'
print(x, maxtime, test=c("aalen", "nrisk"), scale=1, ...)
```

## Arguments

|                |                                                                                                                                                                                                                                                       |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>       | the result of a call to the aareg function                                                                                                                                                                                                            |
| <b>maxtime</b> | the upper time point to be used in the test for non-zero slope                                                                                                                                                                                        |
| <b>test</b>    | the weighting to be used in the test for non-zero slope. The default weights are based on the variance of each coefficient, as a function of time. The alternative weight is proportional to the number of subjects still at risk at each time point. |
| <b>scale</b>   | scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10-4); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read.                                    |
| <b>...</b>     | for future methods                                                                                                                                                                                                                                    |

## Details

The estimated increments in the coefficient estimates can become quite unstable near the end of follow-up, due to the small number of observations still at risk in a data set. Thus, the test for slope will sometimes be more powerful if this last 'tail' is excluded.

## Value

the calling argument is returned.

## Side Effects

the results of the fit are displayed.

| ...                | for future results                                                                                                                                                    |

## Details

The mean and its variance are based on a truncated estimator. That is, if the last observation(s) is not a death, then the survival curve estimate does not go to zero and the mean is undefined. There are four possible approaches, which are selected by the `rmean` option. The first is to set the upper limit to a constant, e.g., `rmean=365`. In this case the reported mean would be the expected number of days, out of the first 365, that would be experienced by each group. This is useful if interest focuses on a fixed period. Other options are "none" (no estimate), "common" and "individual". For the last of these, the mean is computed as the area under the curve, over the range from 0 to the maximum observed time for that curve. Since the end point is random, values for different curves are not comparable and the printed standard errors are an underestimate as they do not take into account this random variation. This option is provided mainly for backwards compatibility, as this estimate was the default (only) one in earlier releases of the code. The "common" option uses the maximum time for all curves in the object as a common upper limit for the auc calculation.

The median and its confidence interval are defined by drawing a horizontal line at 0.5 on the plot of the survival curve and its confidence bands. The intersection of the line with the lower CI band defines the lower limit for the median's interval, and similarly for the upper band. If any of the intersections is not a point, then we use the smallest point of intersection, e.g., if the survival curve were exactly equal to 0.5 over an interval.

## Value

`x`, with the invisible flag set to prevent printing. (The default for all print functions in R is to return the object passed to them; `print.survfit` follows the pattern. If you want to capture these printed results for further processing, see the `table` component of `summary.survfit`.)

## Side Effects

The number of observations, the number of events, the median survival with its confidence interval, and optionally the restricted mean survival (`rmean`) and its standard error, are printed. If there are multiple curves, there is one line of output for each.

**pspline***Smoothing splines using a pspline basis***Description**

Specifies a penalised spline basis for the predictor. This is done by fitting a comparatively small set of splines and penalising the integrated second derivative. Traditional smoothing splines use one basis per observation, but several authors have pointed out that the final results of the fit are indistinguishable for any number of basis functions greater than about 2-3 times the degrees of freedom. Eilers and Marx point out that if the basis functions are evenly spaced, this leads to significant computational simplifications.

**Usage**

```
pspline(x, df=4, theta, nterm=2.5 * df, degree=3, eps=0.1, method,
Boundary.knots=range(x), intercept=FALSE, penalty=TRUE, ...)

psplineinverse(x)
```

**Arguments**

|                       |                                                                                                                                                                                                                                                                                                                              |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>              | for pspline: a covariate vector. The function does not apply to factor variables.<br>For psplineinverse x will be the result of a pspline call.                                                                                                                                                                              |
| <b>df</b>             | the desired degrees of freedom. One of the arguments <b>df</b> or <b>theta</b> must be given, but not both. If <b>df</b> =0, then the AIC = (loglik -df) is used to choose an "optimal" degrees of freedom. If AIC is chosen, then an optional argument 'caic=T' can be used to specify the corrected AIC of Hurvich et. al. |
| <b>theta</b>          | roughness penalty for the fit. It is a monotone function of the degrees of freedom, with <b>theta</b> =1 corresponding to a linear fit and <b>theta</b> =0 to an unconstrained fit of <b>nterm</b> degrees of freedom.                                                                                                       |
| <b>nterm</b>          | number of splines in the basis                                                                                                                                                                                                                                                                                               |
| <b>degree</b>         | degree of splines                                                                                                                                                                                                                                                                                                            |
| <b>eps</b>            | accuracy for <b>df</b>                                                                                                                                                                                                                                                                                                       |
| <b>method</b>         | the method for choosing the tuning parameter <b>theta</b> . If <b>theta</b> is given, then 'fixed' is assumed. If the degrees of freedom is given, then 'df' is assumed. If <b>method='aic'</b> then the degrees of freedom is chosen automatically using Akaike's information criterion.                                    |
| <b>...</b>            | optional arguments to the control function                                                                                                                                                                                                                                                                                   |
| <b>Boundary.knots</b> | the spline is linear beyond the boundary knots. These default to the range of the data.                                                                                                                                                                                                                                      |
| <b>intercept</b>      | if TRUE, the basis functions include the intercept.                                                                                                                                                                                                                                                                          |
| <b>penalty</b>        | if FALSE a large number of attributes having to do with penalized fits are excluded. Most useful for exploring the code so as to return a matrix with few added attributes.                                                                                                                                                  |

**Value**

Object of class **pspline**, **coxph.penalty** containing the spline basis, with the appropriate attributes to be recognized as a penalized term by the **coxph** or **survreg** functions.

For **psplineinverse** the original **x** vector is reconstructed.

pyears

*Person Years*

## Description

This function computes the person-years of follow-up time contributed by a cohort of subjects, stratified into subgroups. It also computes the number of subjects who contribute to each cell of the output table, and optionally the number of events and/or expected number of events in each cell.

## Usage

```
pyears(formula, data, weights, subset, na.action, rmap,
 ratetable, scale=365.25, expect=c('event', 'pyears'),
 model=FALSE, x=FALSE, y=FALSE, data.frame=FALSE)
```

## Arguments

- |         |                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula | a formula object. The response variable will be a vector of follow-up times for each subject, or a Surv object containing the survival time and an event indicator. The predictors consist of optional grouping variables separated by + operators (exactly as in survfit), time-dependent grouping variables such as age (specified with tcut), and optionally a ratetable term. This latter matches each subject to his/her expected cohort. |
| data    | a data frame in which to interpret the variables named in the formula, or in the subset and the weights argument.                                                                                                                                                                                                                                                                                                                              |
| weights | case weights.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| subset  | expression saying that only a subset of the rows of the data should be used in the fit.                                                                                                                                                                                                                                                                                                                                                        |

|                          |                                                                                                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>na.action</code>   | a missing-data filter function, applied to the <code>model.frame</code> , after any subset argument has been used. Default is <code>options()\$na.action</code> . |
| <code>rmap</code>        | an optional list that maps data set names to the ratetable names. See the details section below.                                                                  |
| <code>ratetable</code>   | a table of event rates, such as <code>survexp.uswhite</code> .                                                                                                    |
| <code>scale</code>       | a scaling for the results. As most rate tables are in units/day, the default value of 365.25 causes the output to be reported in years.                           |
| <code>expect</code>      | should the output table include the expected number of events, or the expected number of person-years of observation. This is only valid with a rate table.       |
| <code>data.frame</code>  | return a data frame rather than a set of arrays.                                                                                                                  |
| <code>model, x, y</code> | If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result.          |

## Details

Because `pyears` may have several time variables, it is necessary that all of them be in the same units. For instance, in the call

```
py <- pyears(futime ~ rx, rmap=list(age=age, sex=sex, year=entry.dt),
 ratetable=survexp.us)
```

the natural unit of the ratetable is hazard per day, it is important that `futime`, `age` and `entry.dt` all be in days. Given the wide range of possible inputs, it is difficult for the routine to do sanity checks of this aspect.

The ratetable being used may have different variable names than the user's data set, this is dealt with by the `rmap` argument. The rate table for the above calculation was `survexp.us`, a call to `summary{survexp.us}` reveals that it expects to have variables `age` = age in days, `sex`, and `year` = the date of study entry, we create them in the `rmap` line. The `sex` variable is not mapped, therefore the code assumes that it exists in `mydata` in the correct format. (Note: for factors such as `sex`, the program will match on any unique abbreviation, ignoring case.)

A special function `tcut` is needed to specify time-dependent cutpoints. For instance, assume that `age` is in years, and that the desired final arrays have as one of their margins the `age` groups 0-2, 2-10, 10-25, and 25+. A subject who enters the study at age 4 and remains under observation for 10 years will contribute follow-up time to both the 2-10 and 10-25 subsets. If `cut(age, c(0,2,10,25,100))` were used in the formula, the subject would be classified according to his starting age only. The `tcut` function has the same arguments as `cut`, but produces a different output object which allows the `pyears` function to correctly track the subject.

The results of `pyears` are normally used as input to further calculations. The `print` routine, therefore, is designed to give only a summary of the table.

## Value

a list with components:

|                     |                                                                                                                                                                                                                                                  |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pyears</code> | an array containing the person-years of exposure. (Or other units, depending on the rate table and the <code>scale</code> ). The dimension and dimensions of the array correspond to the variables on the right hand side of the model equation. |
| <code>n</code>      | an array containing the number of subjects who contribute time to each cell of the <code>pyears</code> array.                                                                                                                                    |

|           |                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| event     | an array containing the observed number of events. This will be present only if the response variable is a Surv object.                                                                                                                                  |
| expected  | an array containing the expected number of events (or person years if expect = "pyears"). This will be present only if there was a ratetable term.                                                                                                       |
| data      | if the data.frame option was set, a data frame containing the variables n, event, pyears and event that supplants the four arrays listed above, along with variables corresponding to each dimension. There will be one row for each cell in the arrays. |
| offtable  | the number of person-years of exposure in the cohort that was not part of any cell in the pyears array. This is often useful as an error check; if there is a mismatch of units between two variables, nearly all the person years may be off table.     |
| summary   | a summary of the rate-table matching. This is also useful as an error check.                                                                                                                                                                             |
| call      | an image of the call to the function.                                                                                                                                                                                                                    |
| na.action | the na.action attribute contributed by an na.action routine, if any.                                                                                                                                                                                     |

Look at progression rates jointly by calendar date and age
#
temp.yr <- tcut(mgus$dxyr, 55:92, labels=as.character(55:91))
temp.age <- tcut(mgus$age, 34:101, labels=as.character(34:100))
ptime <- ifelse(is.na(mgus$pctime), mgus$futime, mgus$pctime)
pstat <- ifelse(is.na(mgus$pctime), 0, 1)
pfit <- pyears(Surv(ptime/365.25, pstat) ~ temp.yr + temp.age + sex, mgus,
 data.frame=TRUE)
Turn the factor back into numerics for regression
tdata <- pfit$data
tdata$age <- as.numeric(as.character(tdata$temp.age))
tdata$year<- as.numeric(as.character(tdata$temp.yr))
fit1 <- glm(event ~ year + age+ sex +offset(log(pyyears)),
 data=tdata, family=poisson)
Not run:
fit a gam model
gfit.m <- gam(y ~ s(age) + s(year) + offset(log(time)),
 family = poisson, data = tdata)

End(Not run)

Example #2 Create the hearta data frame:
hearta <- by(heart, heart$id,
 function(x)x[x$stop == max(x$stop),])
hearta <- do.call("rbind", hearta)
Produce pyears table of death rates on the surgical arm
The first is by age at randomization, the second by current age
fit1 <- pyears(Surv(stop/365.25, event) ~ cut(age + 48, c(0,50,60,70,100)) +
 surgery, data = hearta, scale = 1)
fit2 <- pyears(Surv(stop/365.25, event) ~ tcut(age + 48, c(0,50,60,70,100)) +
 surgery, data = hearta, scale = 1)
fit1$event/fit1$pyears #death rates on the surgery and non-surg arm
```

```
fit2$event/fit2$pyears #death rates on the surgery and non-surg arm
```

**quantile.survfit**      *Quantiles from a survfit object*

### Description

Retrieve quantiles and confidence intervals for them from a survfit object.

### Usage

```
S3 method for class 'survfit'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
 tolerance= sqrt(.Machine$double.eps), ...)
S3 method for class 'survfitms'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
 tolerance= sqrt(.Machine$double.eps), ...)
```

### Arguments

|                        |                                                                                    |
|------------------------|------------------------------------------------------------------------------------|
| <code>x</code>         | a result of the survfit function                                                   |
| <code>probs</code>     | numeric vector of probabilities with values in [0,1]                               |
| <code>conf.int</code>  | should lower and upper confidence limits be returned?                              |
| <code>tolerance</code> | tolerance for checking that the survival curve exactly equals one of the quantiles |
| <code>...</code>       | optional arguments for other methods                                               |

### Details

The  $k$ th quantile for a survival curve  $S(t)$  is the location at which a horizontal line at height  $p=1-k$  intersects the plot of  $S(t)$ . Since  $S(t)$  is a step function, it is possible for the curve to have a horizontal segment at exactly  $1-k$ , in which case the midpoint of the horizontal segment is returned. This mirrors the standard behavior of the median when data is uncensored. If the survival curve does not fall to  $1-k$ , then that quantile is undefined.

In order to be consistent with other quantile functions, the argument `prob` of this function applies to the cumulative distribution function  $F(t) = 1-S(t)$ .

Confidence limits for the values are based on the intersection of the horizontal line at  $1-k$  with the upper and lower limits for the survival curve. Hence confidence limits use the same  $p$ -value as was in effect when the curve was created, and will differ depending on the `conf.type` option of `survfit`. If the survival curves have no confidence bands, confidence limits for the quantiles are not available.

When a horizontal segment of the survival curve exactly matches one of the requested quantiles the returned value will be the midpoint of the horizontal segment; this agrees with the usual definition of a median for uncensored data. Since the survival curve is computed as a series of products, however, there may be round off error. Assume for instance a sample of size 20 with no tied times and no censoring. The survival curve after the 10th death is  $(19/20)(18/19)(17/18) \dots (10/11) = 10/20$ , but the computed result will not be exactly 0.5. Any horizontal segment whose absolute difference with a requested percentile is less than `tolerance` is considered to be an exact match.

**Value**

The quantiles will be a vector if the `survfit` object contains only a single curve, otherwise it will be a matrix or array. In this case the last dimension will index the quantiles.

If confidence limits are requested, then result will be a list with components `quantile`, `lower`, and `upper`, otherwise it is the vector or matrix of quantiles.

**Examples**

```
fit <- survfit(Surv(time, status) ~ ph.ecog, data=lung)
quantile(fit)

cfit <- coxph(Surv(time, status) ~ age + strata(ph.ecog), data=lung)
csurv<- survfit(cfit, newdata=data.frame(age=c(40, 60, 80)),
 conf.type ="none")
temp <- quantile(csurv, 1:5/10)
temp[2,3,] # quantiles for second level of ph.ecog, age=80
quantile(csurv[2,3], 1:5/10) # quantiles of a single curve, same result
```

---

ratetable

*Ratetable reference in formula*

---

**Description**

This function matches variable names in data to those in a ratetable for [survexp](#)

**Usage**

`ratetable(...)`

**Arguments**

... tags matching dimensions of the ratetable and variables in the data frame (see example)

**Value**

A data frame

**See Also**

[survexp](#), [survexp.us](#), [is.ratetable](#)

## Examples

```
fit <- survfit(Surv(time, status) ~ sex, pbc, subset=1:312)

The data set does not have entry date, use the midpoint of the study
efit <- survexp(~ ratetable(sex=sex, age=age*365.35, year=as.Date('1979/1/1')) +
 sex, data=pbc, times=(0:24)*182)
Not run:
plot(fit, mark.time=F, xscale=365.25, xlab="Years post diagnosis",
 ylab="Survival")
lines(efit, col=2, xscale=365.25) # Add the expected survival line

End(Not run)
```

## ratetableDate

*Convert date objects to ratetable form*

## Description

This method converts dates from various forms into the internal form used in `ratetable` objects.

## Usage

```
ratetableDate(x)
```

## Arguments

- |                |                                                                                                 |
|----------------|-------------------------------------------------------------------------------------------------|
| <code>x</code> | a date. The function currently has methods for Date, date, POSIXt, timeDate, and chron objects. |
|----------------|-------------------------------------------------------------------------------------------------|

## Details

This function is useful for those who create new ratetables, but is normally invisible to users. It is used internally by the `survexp` and `pyears` functions to map the various date formats; if a new method is added then those routines will automatically be adapted to the new date type.

## Value

a numeric vector, the number of days since 1/1/1960.

## Author(s)

Terry Therneau

**ratetables***Census Data Sets for the Expected Survival and Person Years Functions*

---

**Description**

Census data sets for the expected survival and person years functions.

**Details**

**us** total United States population, by age and sex, 1960 to 1980.

**uswhite** United States white population, by age and sex, 1950 to 1980. This is no longer included, but can be extracted from **survexp.usr** as shown in the examples.

**usr** United States population, by age, sex and race, 1960 to 1980. Race is white, nonwhite, or black. For 1960 and 1970 the black population values were not reported separately, so the nonwhite values were used.

**mn** total Minnesota population, by age and sex, 1970 and 1980.

**mnwhite** Minnesota white population, by age and sex, 1960 to 1980.

**fl** total Florida population, by age and sex, 1970 and 1980.

**flr** Florida population, by age, sex and race, 1970-1980. Race is white, nonwhite, or black. For 1970 the black population values were not reported separately, so the nonwhite values were used.

**az** total Arizona population, by age and sex, 1970 and 1980.

**azr** Arizona population, by age, sex and race, 1970-1980. Race is white versus nonwhite. For 1970 the nonwhite population values were not reported separately. In order to make the rate table be a matrix, the 1980 values were repeated. (White and non-white values are quite different).

Each of these tables contains the daily hazard rate for a matched subject from the population, defined as  $-\log(1 - q)/365.24$  where  $q$  is the 1 year probability of death as reported in the original tables. For age 25 in 1970, for instance,  $p = 1 - q$  is the probability that a subject who becomes 25 years of age in 1970 will achieve his/her 26th birthday. The tables are recast in terms of hazard per day entirely for computational convenience. (The fraction .24 in the denominator is based on 24 leap years per century.)

Each table is stored as an array, with additional attributes, and can be subset and manipulated as standard S arrays. Interpolation between calendar years is done “on the fly” by the **survexp** routine.

Some of the deficiencies, e.g., 1970 Arizona non-white, are a result of local (Mayo Clinic) conditions. The data probably exists, but we don’t have a copy it in the library.

The tables have been augmented to contain extrapolated values for 1990 and 2000. The details can be found in Mayo Clinic Biostatistics technical report 63 at <http://www.mayo.edu/hsr/tech rpt.html>.

**Examples**

```
survexp.uswhite <- survexp.usr[,"white",]
```

**residuals.coxph** *Calculate Residuals for a ‘coxph’ Fit*

## Description

Calculates martingale, deviance, score or Schoenfeld residuals for a Cox proportional hazards model.

## Usage

```
S3 method for class 'coxph'
residuals(object,
 type=c("martingale", "deviance", "score", "schoenfeld",
 "dfbeta", "dfbetas", "scaledsch", "partial"),
 collapse=FALSE, weighted=FALSE, ...)

S3 method for class 'coxph.null'
residuals(object,
 type=c("martingale", "deviance", "score", "schoenfeld"),
 collapse=FALSE, weighted=FALSE, ...)
```

## Arguments

- object an object inheriting from class `coxph`, representing a fitted Cox regression model. Typically this is the output from the `coxph` function.
- type character string indicating the type of residual desired. Possible values are "martingale", "deviance", "score", "schoenfeld", "dfbeta", "dfbetas", and "scaledsch". Only enough of the string to determine a unique match is required.
- collapse vector indicating which rows to collapse (sum) over. In time-dependent models more than one row data can pertain to a single individual. If there were 4 individuals represented by 3, 1, 2 and 4 rows of data respectively, then `collapse=c(1,1,1, 2, 3,3, 4,4,4,4)` could be used to obtain per subject rather than per observation residuals.
- weighted if TRUE and the model was fit with case weights, then the weighted residuals are returned.
- ... other unused arguments

### Value

For martingale and deviance residuals, the returned object is a vector with one element for each subject (without collapse). For score residuals it is a matrix with one row per subject and one column per variable. The row order will match the input data for the original fit. For Schoenfeld residuals, the returned object is a matrix with one row for each event and one column per variable. The rows are ordered by time within strata, and an attribute `strata` is attached that contains the number of observations in each strata. The scaled Schoenfeld residuals are used in the `cox.zph` function.

The score residuals are each individual's contribution to the score vector. Two transformations of this are often more useful: `dfbeta` is the approximate change in the coefficient vector if that observation were dropped, and `dfbetas` is the approximate change in the coefficients, scaled by the standard error for the coefficients.

### NOTE

For deviance residuals, the status variable may need to be reconstructed. For score and Schoenfeld residuals, the X matrix will need to be reconstructed.

 data=heart)
mresid <- resid(fit, collapse=heart$id)
```

**residuals.survreg**      *Compute Residuals for 'survreg' Objects*

### Description

This is a method for the function [residuals](#) for objects inheriting from class `survreg`.

### Usage

```
S3 method for class 'survreg'
residuals(object, type=c("response", "deviance", "dfbeta", "dfbetas",
"working", "ldcase", "ldresp", "ldshape", "matrix"), rsigma=TRUE,
collapse=FALSE, weighted=FALSE, ...)
```

**Arguments**

|          |                                                                                                                                                                                                                                   |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object   | an object inheriting from class <code>survreg</code> .                                                                                                                                                                            |
| type     | type of residuals, with choices of "response", "deviance", "dfbeta", "dfbetas", "working", "ldcase", "lsresp", "ldshape", and "matrix". See the LaTeX documentation ( <code>survival/doc/survival.ps.gz</code> ) for more detail. |
| rsigma   | include the scale parameters in the variance matrix, when doing computations. (I can think of no good reason not to).                                                                                                             |
| collapse | optional vector of subject groups. If given, this must be of the same length as the residuals, and causes the result to be per group residuals.                                                                                   |
| weighted | give weighted residuals? Normally residuals are unweighted.                                                                                                                                                                       |
| ...      | other unused arguments                                                                                                                                                                                                            |

**Value**

A vector or matrix of residuals is returned. Response residuals are on the scale of the original data, working residuals are on the scale of the linear predictor, and deviance residuals are on log-likelihood scale. The dfbeta residuals are a matrix, where the  $i$ th row gives the approximate change in the coefficients due to the addition of subject  $i$ . The dfbetas matrix contains the dfbeta residuals, with each column scaled by the standard deviation of that coefficient.

The matrix type produces a matrix based on derivatives of the log-likelihood function. Let  $L$  be the log-likelihood,  $p$  be the linear predictor  $X\beta$ , and  $s$  be  $\log(\sigma)$ . Then the 6 columns of the matrix are  $L$ ,  $dL/dp, \partial^2 L/\partial p^2, dL/ds, \partial^2 L/\partial s^2$  and  $\partial^2 L/\partial p \partial s$ . Diagnostics based on these quantities are discussed in an article by Escobar and Meeker. The main ones are the likelihood displacement residuals for perturbation of a case weight (ldcase), the response value (ldresp), and the shape.

**Examples**

```
fit <- survreg(Surv(time,status) ~x, aml)
rr <- residuals(fit, type='matrix')
```

ridge

*Ridge regression*

**Description**

When used in a `coxph` or `survreg` model formula, specifies a ridge regression term. The likelihood is penalised by  $\theta/2$  times the sum of squared coefficients. If `scale=T` the penalty is calculated for coefficients based on rescaling the predictors to have unit variance. If `df` is specified then `theta` is chosen based on an approximate degrees of freedom.

**Usage**

```
ridge(..., theta, df=nvar/2, eps=0.1, scale=TRUE)
```

**Arguments**

|       |                                                     |
|-------|-----------------------------------------------------|
| ...   | predictors to be ridged                             |
| theta | penalty is theta/2 time sum of squared coefficients |
| df    | Approximate degrees of freedom                      |
| eps   | Accuracy required for df                            |
| scale | Scale variables before applying penalty?            |

**Value**

An object of class `coxph.penalty` containing the data and control functions.

|--------|------------------------------------------|
| strata | <i>Identify Stratification Variables</i> |
|--------|------------------------------------------|

---

## Description

This is a special function used in the context of the Cox survival model. It identifies stratification variables when they appear on the right hand side of a formula.

## Usage

```
strata(..., na.group=FALSE, shortlabel=FALSE, sep=', ')
```

## Arguments

|            |                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------|
| ...        | any number of variables. All must be the same length.                                              |
| na.group   | a logical variable, if TRUE, then missing values are treated as a distinct level of each variable. |
| shortlabel | if TRUE omit variable names from resulting factor labels                                           |
| sep        | the character used to separate groups, in the created label                                        |

## Details

The result is identical to the `interaction` function, but for the labeling of the factors (`strata` is more verbose).

## Value

a new factor, whose levels are all possible combinations of the factors supplied as arguments.

a<-factor(rep(1:3,4))
b<-factor(rep(1:4,3))
levels(strata(a))
levels(strata(a,b,shortlabel=TRUE))

coxph(Surv(futime, fustat) ~ age + strata(rx), data=ovarian)
```

**summary.aareg**

*Summarize an aareg fit*

**Description**

Creates the overall test statistics for an Aalen additive regression model

**Usage**

```
S3 method for class 'aareg'
summary(object, maxtime, test=c("aalen", "nrisk"), scale=1,...)
```

**Arguments**

|                |                                                                                                                                                                                                                    |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b>  | the result of a call to the aareg function                                                                                                                                                                         |
| <b>maxtime</b> | truncate the input to the model at time "maxtime"                                                                                                                                                                  |
| <b>test</b>    | the relative time weights that will be used to compute the test                                                                                                                                                    |
| <b>scale</b>   | scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10-4); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read. |
| <b>...</b>     | for future methods                                                                                                                                                                                                 |

**Details**

It is not uncommon for the very right-hand tail of the plot to have large outlying values, particularly for the standard error. The **maxtime** parameter can then be used to truncate the range so as to avoid these. This gives an updated value for the test statistics, without refitting the model.

The slope is based on a weighted linear regression to the cumulative coefficient plot, and may be a useful measure of the overall size of the effect. For instance when two models include a common variable, "age" for instance, this may help to assess how much the fit changed due to the other variables, in leiu of overlaying the two plots. (Of course the plots are often highly non-linear, so it is only a rough substitute). The slope is not directly related to the test statistic, as the latter is invariant to any monotone transformation of time.

**Value**

a list is returned with the following components

|                       |                                                                                                                                                                  |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>table</b>          | a matrix with rows for the intercept and each covariate, and columns giving a slope estimate, the test statistic, it's standard error, the z-score and a p-value |
| <b>test</b>           | the time weighting used for computing the test statistics                                                                                                        |
| <b>test.statistic</b> | the vector of test statistics                                                                                                                                    |
| <b>test.var</b>       | the model based variance matrix for the test statistic                                                                                                           |
| <b>test.var2</b>      | optionally, a robust variance matrix for the test statistic                                                                                                      |
| <b>chisq</b>          | the overall test (ignoring the intercept term) for significance of any variable                                                                                  |
| <b>n</b>              | a vector containing the number of observations, the number of unique death times used in the computation, and the total number of unique death times             |

---

**summary.coxph** *Summary method for Cox models*

---

### Description

Produces a summary of a fitted coxph model

### Usage

```
S3 method for class 'coxph'
summary(object, conf.int=0.95, scale=1,...)
```

### Arguments

|          |                                                                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------|
| object   | the result of a coxph fit                                                                                                                  |
| conf.int | level for computation of the confidence intervals. If set to FALSE no confidence intervals are printed                                     |
| scale    | vector of scale factors for the coefficients, defaults to 1. The confidence limits are for the risk change associated with one scale unit. |
| ...      | for future methods                                                                                                                         |

### Value

An object of class **summary.coxph**.

### See Also

**coxph**, **print.coxph**

### Examples

```
fit <- coxph(Surv(time, status) ~ age + sex, lung)
summary(fit)
Not run:

Score (logrank) test = 13.7 on 2 df, p=0.00105

End(Not run)
```

---

**summary.survexp** *Summary function for a survexp object*

---

**Description**

Returns a list containing the values of the survival at specified times.

**Usage**

```
S3 method for class 'survexp'
summary(object, times, scale = 1, ...)
```

**Arguments**

|        |                                                                                                                                              |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------|
| object | the result of a call to the survexp function                                                                                                 |
| times  | vector of times; the returned matrix will contain 1 row for each time. Missing values are not allowed.                                       |
| scale  | numeric value to rescale the survival time, e.g., if the input data to survfit were in days, scale = 365.25 would scale the output to years. |
| ...    | For future methods                                                                                                                           |

**Details**

A primary use of this function is to retrieve survival at fixed time points, which will be properly interpolated by the function.

**Value**

a list with the following components:

|        |                                                                                                                                                                                                                                                                                    |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| surv   | the estimate of survival at time t.                                                                                                                                                                                                                                                |
| time   | the timepoints on the curve.                                                                                                                                                                                                                                                       |
| n.risk | In expected survival each subject from the data set is matched to a hypothetical person from the parent population, matched on the characteristics of the parent population. The number at risk is the number of those hypothetical subject who are still part of the calculation. |

**summary.survfit**      *Summary of a Survival Curve*

---

## Description

Returns a list containing the survival curve, confidence limits for the curve, and other information.

## Usage

```
S3 method for class 'survfit'
summary(object, times=, censored=FALSE, scale=1,
 extend=FALSE, rmean=getOption('survfit.rmean'), ...)
```

## Arguments

|                 |                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>object</b>   | the result of a call to the <code>survfit</code> function.                                                                                                                                                                                                                                                                                            |
| <b>times</b>    | vector of times; the returned matrix will contain 1 row for each time. This must be in increasing order and missing values are not allowed. If <code>censored=T</code> , the default <code>times</code> vector contains all the unique times in <code>fit</code> , otherwise the default <code>times</code> vector uses only the event (death) times. |
| <b>censored</b> | logical value: should the censoring times be included in the output? This is ignored if the <code>times</code> argument is present.                                                                                                                                                                                                                   |
| <b>scale</b>    | numeric value to rescale the survival time, e.g., if the input data to <code>survfit</code> were in days, <code>scale = 365.25</code> would scale the output to years.                                                                                                                                                                                |
| <b>extend</b>   | logical value: if TRUE, prints information for all specified <code>times</code> , even if there are no subjects left at the end of the specified <code>times</code> . This is only valid if the <code>times</code> argument is present.                                                                                                               |
| <b>rmean</b>    | Show restricted mean: see <a href="#">print.survfit</a> for details                                                                                                                                                                                                                                                                                   |
| <b>...</b>      | for future methods                                                                                                                                                                                                                                                                                                                                    |

## Value

a list with the following components:

|                  |                                                                                                                                                                                                                                                                                     |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>surv</b>      | the estimate of survival at time t+0.                                                                                                                                                                                                                                               |
| <b>time</b>      | the timepoints on the curve.                                                                                                                                                                                                                                                        |
| <b>n.risk</b>    | the number of subjects at risk at time t-0 (but see the comments on weights in the <code>survfit</code> help file).                                                                                                                                                                 |
| <b>n.event</b>   | if the <code>times</code> argument is missing, then this column is the number of events that occurred at time t. Otherwise, it is the cumulative number of events that have occurred since the last time listed until time t+0.                                                     |
| <b>n.entered</b> | This is present only for counting process survival data. If the <code>times</code> argument is missing, this column is the number of subjects that entered at time t. Otherwise, it is the cumulative number of subjects that have entered since the last time listed until time t. |

|                              |                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n.exit.censored</code> | if the <code>times</code> argument is missing, this column is the number of subjects that left without an event at time $t$ . Otherwise, it is the cumulative number of subjects that have left without an event since the last time listed until time $t+0$ . This is only present for counting process survival data.                                 |
| <code>std.err</code>         | the standard error of the survival value.                                                                                                                                                                                                                                                                                                               |
| <code>conf.int</code>        | level of confidence for the confidence intervals of survival.                                                                                                                                                                                                                                                                                           |
| <code>lower</code>           | lower confidence limits for the curve.                                                                                                                                                                                                                                                                                                                  |
| <code>upper</code>           | upper confidence limits for the curve.                                                                                                                                                                                                                                                                                                                  |
| <code>strata</code>          | indicates stratification of curve estimation. If <code>strata</code> is not <code>NULL</code> , there are multiple curves in the result and the <code>surv</code> , <code>time</code> , <code>n.risk</code> , etc. vectors will contain multiple curves, pasted end to end. The levels of <code>strata</code> (a factor) are the labels for the curves. |
| <code>call</code>            | the statement used to create the <code>fit</code> object.                                                                                                                                                                                                                                                                                               |
| <code>na.action</code>       | same as for <code>fit</code> , if present.                                                                                                                                                                                                                                                                                                              |
| <code>table</code>           | table of information that is returned from <code>print.survfit</code> function.                                                                                                                                                                                                                                                                         |
| <code>type</code>            | type of data censoring. Passed through from the <code>fit</code> object.                                                                                                                                                                                                                                                                                |

Surv

*Create a Survival Object*

## Description

Create a survival object, usually used as a response variable in a model formula. Argument matching is special for this function, see Details below.

## Usage

```
Surv(time, time2, event,
 type=c('right', 'left', 'interval', 'counting', 'interval2', 'mstate'),
 origin=0)
is.Surv(x)
```

### Arguments

|        |                                                                                                                                                                                                                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| time   | for right censored data, this is the follow up time. For interval data, the first argument is the starting time for the interval.                                                                                                                                                                                                                         |
| event  | The status indicator, normally 0=alive, 1=dead. Other choices are TRUE/FALSE (TRUE = death) or 1/2 (2=death). For interval censored data, the status indicator is 0=right censored, 1=event at time, 2=left censored, 3=interval censored. Although unusual, the event indicator can be omitted, in which case all subjects are assumed to have an event. |
| time2  | ending time of the interval for interval censored or counting process data only. Intervals are assumed to be open on the left and closed on the right, (start, end]. For counting process data, event indicates whether an event occurred at the end of the interval.                                                                                     |
| type   | character string specifying the type of censoring. Possible values are "right", "left", "counting", "interval", "interval2" or "mstate".                                                                                                                                                                                                                  |
| origin | for counting process data, the hazard function origin. This option was intended to be used in conjunction with a model containing time dependent strata in order to align the subjects properly when they cross over from one strata to another, but it has rarely proven useful.                                                                         |
| x      | any R object.                                                                                                                                                                                                                                                                                                                                             |

### Details

When the type argument is missing the code assumes a type based on the following rules:

- If there are two unnamed arguments, they will match time and event in that order. If there are three unnamed arguments they match time, time2 and event.
- If the event variable is a factor then type mstate is assumed. Otherwise type right if there is no time2 argument, and type counting if there is.

As a consequence the type argument can usually be omitted.

When the survival type is "mstate" then the status variable will be treated as a factor. The first level of the factor is taken to represent censoring and remaining ones a transition to the given state.

Interval censored data can be represented in two ways. For the first use type = interval and the codes shown above. In that usage the value of the time2 argument is ignored unless event=3. The second approach is to think of each observation as a time interval with (-infinity, t) for left censored, (t, infinity) for right censored, (t,t) for exact and (t1, t2) for an interval. This is the approach used for type = interval2, with NA taking the place of infinity. It has proven to be the more useful.

Presently, the only methods allowing interval censored data are the parametric models computed by `survreg` and survival curves computed by `survfit`; for both of these, the distinction between open and closed intervals is unimportant. The distinction is important for counting process data and the Cox model.

The function tries to distinguish between the use of 0/1 and 1/2 coding for left and right censored data using `if (max(status)==2)`. If 1/2 coding is used and all the subjects are censored, it will guess wrong. In any questionable case it is safer to use logical coding, e.g., `Surv(time, status==3)` would indicate that a 3 is the code for an event.

For multi-state survival (type= "mstate") the status variable can have multiple levels. The first of these will stand for censoring, and the others for various event types, e.g., causes of death.

Surv objects can be subscripted either as an object, e.g. `x[1:3]` using a single subscript; in which case the drop argument is ignored; or as a matrix, using two arguments. If the second subscript

is missing and `drop=F` (the default), the result of the subscripting will be a `Surv` object, e.g., `x[1:3,,drop=F]`, otherwise the result will be a matrix (or vector), in accordance with the default behavior for subscripting matrices.

### Value

An object of class `Surv`. There are methods for `print`, `is.na`, and subscripting survival objects. `Surv` objects are implemented as a matrix of 2 or 3 columns.

In the case of `is.Surv`, a logical value `TRUE` if `x` inherits from class "Surv", otherwise an `FALSE`.

### Examples

```
with(lung, Surv(time, status))
Surv(heart$start, heart$stop, heart$event)
```

`survConcordance`      *Compute a concordance measure.*

### Description

This function computes the concordance between a right-censored survival time and a single continuous covariate

### Usage

```
survConcordance(formula, data, weights, subset, na.action)
```

### Arguments

|                                       |                                                                                                                                                                                     |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>                  | a formula with a survival time on the left and a single covariate on the right, along with an optional <code>strata()</code> term. The left hand term can also be a numeric vector. |
| <code>data</code>                     | a data frame                                                                                                                                                                        |
| <code>weights,subset,na.action</code> | as for <code>coxph</code>                                                                                                                                                           |

### Details

Concordance is defined as  $\text{Pr}(\text{agreement})$  for any two randomly chosen observations, where in this case agreement means that the observation with the shorter survival time of the two also has the larger risk score. The predictor (or risk score) will often be the result of a Cox model or other regression.

For continuous covariates concordance is equivalent to Kendall's tau, and for logistic regression is is equivalent to the area under the ROC curve. A value of 1 signifies perfect agreement, .6-.7 is a common result for survival data, .5 is an agreement that is no better than chance, and .3-.4 is the performance of some stock market analysts.

The computation involves all  $n(n-1)/2$  pairs of data points in the sample. For survival data, however, some of the pairs are incomparable. For instance a pair of times (5+, 8), the first being a censored value. We do not know whether the first survival time is greater than or less than the second. Among observations that are comparable, pairs may also be tied on survival time (but only if both are uncensored) or on the predictor. The final concordance is  $(\text{agree} + \text{tied}/2)/(\text{agree} + \text{disagree} + \text{tied})$ .

There is, unfortunately, one aspect of the formula above that is unclear. Should the count of ties include observations that are tied on survival time  $y$ , tied on the predictor  $x$ , or both? By default the concordance only counts ties in  $x$ , treating tied survival times as incomparable; this agrees with the AUC calculation used in logistic regression. The Goodman-Kruskal Gamma statistic is  $(\text{agree}-\text{disagree})/(\text{agree} + \text{disagree})$ , ignoring ties. It ranges from -1 to +1 similar to a correlation coefficient. Kendall's tau uses ties of both types. All of the components are returned in the result, however, so people can compute other combinations if interested. (If two observations have the same survival and the same  $x$ , they are counted in the tied survival time category).

The algorithm is based on a balanced binary tree, which allows the computation to be done in  $O(n \log n)$  time.

### Value

an object containing the concordance, followed by the number of pairs that agree, disagree, are tied, and are not comparable.

### See Also

`summary.coxph`

### Examples

```
survConcordance(Surv(time, status) ~age, data=lung)

options(na.action=na.exclude)
fit <- coxph(Surv(time, status) ~ ph.ecog + age + sex, lung)
survConcordance(Surv(time, status) ~predict(fit), lung)
Not run:
n=227 (1 observations deleted due to missing values)
Concordance= 0.6371102 , Gamma= 0.2759638
concordant discordant tied risk tied time
 12544 7117 126 28
End(Not run)
```

### Description

Tests if there is a difference between two or more survival curves using the  $G^\rho$  family of tests, or for a single curve against a known alternative.

### Usage

`survdiff(formula, data, subset, na.action, rho=0)`

### Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula expression as for other survival models, of the form <code>Surv(time, status) ~ predictors</code> . For a one-sample test, the predictors must consist of a single <code>offset(sp)</code> term, where <code>sp</code> is a vector giving the survival probability of each subject. For a k-sample test, each unique combination of predictors defines a subgroup. A <code>strata</code> term may be used to produce a stratified test. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the <code>strata</code> function with its <code>na.group=T</code> argument. |
| data      | an optional data frame in which to interpret the variables occurring in the formula.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| subset    | expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating which observation numbers are to be included (or excluded if negative), or a character vector of row names to be included. All observations are included by default.                                                                                                                                                                                                                                                 |
| na.action | a missing-data filter function. This is applied to the <code>model.frame</code> after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| rho       | a scalar parameter that controls the type of test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### Value

a list with components:

|        |                                                                                                                               |
|--------|-------------------------------------------------------------------------------------------------------------------------------|
| n      | the number of subjects in each group.                                                                                         |
| obs    | the weighted observed number of events in each group. If there are strata, this will be a matrix with one column per stratum. |
| exp    | the weighted expected number of events in each group. If there are strata, this will be a matrix with one column per stratum. |
| chisq  | the chisquare statistic for a test of equality.                                                                               |
| var    | the variance matrix of the test.                                                                                              |
| strata | optionally, the number of subjects contained in each stratum.                                                                 |

### METHOD

This function implements the G-rho family of Harrington and Fleming (1982), with weights on each death of  $S(t)^\rho$ , where  $S(t)$  is the Kaplan-Meier estimate of survival. With `rho = 0` this is the log-rank or Mantel-Haenszel test, and with `rho = 1` it is equivalent to the Peto & Peto modification of the Gehan-Wilcoxon test.

If the right hand side of the formula consists only of an offset term, then a one sample test is done. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the `factor` function with its `exclude` argument.

### References

## Examples

```

Two-sample test
survdiff(Surv(futime, fustat) ~ rx,data=ovarian)

Stratified 7-sample test

survdiff(Surv(time, status) ~ pat.karno + strata(inst), data=lung)

Expected survival for heart transplant patients based on
US mortality tables
expect <- survexp(futime ~ ratetable(age=(accept.dt - birth.dt),
 sex=1,year=accept.dt,race="white"), jasa, cohort=FALSE,
 ratetable=survexp.usr)
actual survival is much worse (no surprise)
survdiff(Surv(jasa$futime, jasa$fustat) ~ offset(expect))

```

survexp

*Compute Expected Survival*

## Description

Returns either the expected survival of a cohort of subjects, or the individual expected survival for each subject.

## Usage

```
survexp(formula, data, weights, subset, na.action, rmap, times, cohort=TRUE,
 conditional=FALSE, ratetable=survexp.us, scale=1, npoints,
 se.fit, model=FALSE, x=FALSE, y=FALSE)
```

## Arguments

|                  |                                                                                                                                                                                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>formula</b>   | formula object. The response variable is a vector of follow-up times and is optional. The predictors consist of optional grouping variables separated by the + operator (as in <code>survfit</code> ), and is often ~1, i.e., expected survival for the entire group.                                    |
| <b>data</b>      | data frame in which to interpret the variables named in the <code>formula</code> , <code>subset</code> and <code>weights</code> arguments.                                                                                                                                                               |
| <b>weights</b>   | case weights.                                                                                                                                                                                                                                                                                            |
| <b>subset</b>    | expression indicating a subset of the rows of <code>data</code> to be used in the fit.                                                                                                                                                                                                                   |
| <b>na.action</b> | function to filter missing data. This is applied to the model frame after <code>subset</code> has been applied. Default is <code>options()\$na.action</code> . A possible value for <code>na.action</code> is <code>na.omit</code> , which deletes observations that contain one or more missing values. |
| <b>rmap</b>      | an optional list that maps data set names to the ratetable names. See the details section below.                                                                                                                                                                                                         |
| <b>times</b>     | vector of follow-up times at which the resulting survival curve is evaluated. If absent, the result will be reported for each unique value of the vector of follow-up times supplied in <code>formula</code> .                                                                                           |

|             |                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cohort      | logical value: if FALSE, each subject is treated as a subgroup of size 1. The default is TRUE.                                                                                                                                                                                                                                                     |
| conditional | logical value: if TRUE, the follow-up times supplied in formula are death times and conditional expected survival is computed. If FALSE, the follow-up times are potential censoring times. If follow-up times are missing in formula, this argument is ignored.                                                                                   |
| ratetable   | a table of event rates, such as survexp.uswhite, or a fitted Cox model.                                                                                                                                                                                                                                                                            |
| scale       | numeric value to scale the results. If ratetable is in units/day, scale = 365.25 causes the output to be reported in years.                                                                                                                                                                                                                        |
| npoints     | number of points at which to calculate intermediate results, evenly spaced over the range of the follow-up times. The usual (exact) calculation is done at each unique follow-up time. For very large data sets specifying npoints can reduce the amount of memory and computation required. For a prediction from a Cox model npoints is ignored. |
| se.fit      | compute the standard error of the predicted survival. The default is to compute standard errors whenever possible, which at this time is only for the Ederer method and a Cox model as the rate table.                                                                                                                                             |
| model, x, y | flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments.                                                                                                             |

## Details

Individual expected survival is usually used in models or testing, to ‘correct’ for the age and sex composition of a group of subjects. For instance, assume that birth date, entry date into the study, sex and actual survival time are all known for a group of subjects. The survexp.us population tables contain expected death rates based on calendar year, sex and age. Then

```
haz <- -log(survexp(fu.time ~ 1, data=mydata,
 rmap = list(year=entry.dt, age=(birth.dt-entry.dt)),
 cohort=FALSE))
```

gives for each subject the total hazard experienced up to their observed death time or last follow-up time (variable fu.time) This probability can be used as a rescaled time value in models:

```
glm(status ~ 1 + offset(log(haz)), family=poisson)
glm(status ~ x + offset(log(haz)), family=poisson)
```

In the first model, a test for intercept=0 is the one sample log-rank test of whether the observed group of subjects has equivalent survival to the baseline population. The second model tests for an effect of variable x after adjustment for age and sex.

The ratetable being used may have different variable names than the user’s data set, this is dealt with by the rmap argument. The rate table for the above calculation was survexp.us, a call to summary{survexp.us} reveals that it expects to have variables age = age in days, sex, and year = the date of study entry, we create them in the rmap line. The sex variable is not mapped, therefore the code assumes that it exists in mydata in the correct format. (Note: for factors such as sex, the program will match on any unique abbreviation, ignoring case.)

Cohort survival is used to produce an overall survival curve. This is then added to the Kaplan-Meier plot of the study group for visual comparison between these subjects and the population at large. There are three common methods of computing cohort survival. In the "exact method" of Ederer the

cohort is not censored; this corresponds to having no response variable in the formula. Hakulinen recommends censoring the cohort at the anticipated censoring time of each patient, and Verheul recommends censoring the cohort at the actual observation time of each patient. The last of these is the conditional method. These are obtained by using the respective time values as the follow-up time or response in the formula.

### Value

if cohort=TRUE an object of class survexp, otherwise a vector of per-subject expected survival values. The former contains the number of subjects at risk and the expected survival for the cohort at each requested time.

### Examples

```

Stanford heart transplant data

We don't have sex in the data set, but know it to be nearly all males.

Estimate of conditional survival

survexp(futime ~ 1, rmap=list(sex="male", year=accept.dt,

 age=(accept.dt-birth.dt)), conditional=TRUE, data=jasa)

Estimate of expected survival stratified by prior surgery

survexp(futime ~ surgery, rmap= list(sex="male", year=accept.dt,

 age=(accept.dt-birth.dt)), conditional=TRUE, data=jasa)

Compare the survival curves for the Mayo PBC data to Cox model fit

pfit <- coxph(Surv(time,status>0) ~ trt + log(bili) + log(protome) + age +

 platelet, data=pbc)

plot(survfit(Surv(time, status>0) ~ trt, data=pbc))

lines(survexp(~ trt, ratetable=pfit, data=pbc), col='purple')
```

### Description

Compute expected survival times.

**Usage**

```
survexp.fit(group, x, y, times, death, ratetable)
```

**Arguments**

|           |                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| group     | if there are multiple survival curves this identifies the group, otherwise it is a constant. Must be an integer.                                       |
| x         | A matrix whose columns match the dimensions of the ratetable, in the correct order.                                                                    |
| y         | the follow up time for each subject.                                                                                                                   |
| times     | the vector of times at which a result will be computed.                                                                                                |
| death     | a logical value, if TRUE the conditional survival is computed, if FALSE the cohort survival is computed. See <a href="#">survexp</a> for more details. |
| ratetable | a rate table, such as <a href="#">survexp.uswhite</a> .                                                                                                |

**Details**

For conditional survival *y* must be the time of last follow-up or death for each subject. For cohort survival it must be the potential censoring time for each subject, ignoring death.

For an exact estimate *times* should be a superset of *y*, so that each subject at risk is at risk for the entire sub-interval of time. For a large data set, however, this can use an inordinate amount of storage and/or compute time. If the *times* spacing is more coarse than this, an actuarial approximation is used which should, however, be extremely accurate as long as all of the returned values are  $> .99$ .

For a subgroup of size 1 and *times*  $> y$ , the conditional method reduces to  $\exp(-h)$  where *h* is the expected cumulative hazard for the subject over his/her observation time. This is used to compute individual expected survival.

**Value**

A list containing the number of subjects and the expected survival(s) at each time point. If there are multiple groups, these will be matrices with one column per group.

**Warning**

Most users will call the higher level routine [survexp](#). Consequently, this function has very few error checks on its input arguments.

|                |                               |
|----------------|-------------------------------|
| <b>survfit</b> | <i>Create survival curves</i> |
|----------------|-------------------------------|

---

## Description

This function creates survival curves from either a formula (e.g. the Kaplan-Meier), a previously fitted Cox model, or a previously fitted accelerated failure time model.

## Usage

```
survfit(formula, ...)
```

## Arguments

|                |                                               |
|----------------|-----------------------------------------------|
| <b>formula</b> | either a formula or a previously fitted model |
| <b>...</b>     | other arguments to the specific method        |

## Details

A survival curve is based on a tabulation of the number at risk and number of events at each unique death time. When time is a floating point number the definition of "unique" is subject to interpretation. The code uses factor() to define the set. For further details see the documentation for the appropriate method, i.e., ?survfit.formula or ?survfit.coxph.

## Value

An object of class **survfit** containing one or more survival curves.

## Note

Older releases of the code also allowed the specification for a single curve to omit the right hand of the formula, i.e., ~ 1. Handling this case required some non-standard and fairly fragile manipulations, and this case is no longer supported.

## Author(s)

Terry Therneau

| <code>survfit.coxph</code> | <i>Compute a Survival Curve from a Cox model</i> |
|----------------------------|--------------------------------------------------|

---

### Description

Computes the predicted survivor function for a Cox proportional hazards model.

### Usage

```
S3 method for class 'coxph'
survfit(formula, newdata,
 se.fit=TRUE, conf.int=.95,
 individual=FALSE,
 type,vartype,
 conf.type=c("log","log-log","plain","none"), censor=TRUE, id,
 newstrata, na.action=na.pass, ...)
```

### Arguments

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>formula</code>      | A <code>coxph</code> object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>newdata</code>      | a data frame with the same variable names as those that appear in the <code>coxph</code> formula. It is also valid to use a vector, if the data frame would consist of a single row.<br>The curve(s) produced will be representative of a cohort whose covariates correspond to the values in <code>newdata</code> . Default is the mean of the covariates used in the <code>coxph</code> fit.                                                                                                                                                                                                                                       |
| <code>individual</code>   | This argument has been superseded by the <code>id</code> argument and is present only for backwards compatibility. A logical value indicating whether each row of <code>newdata</code> represents a distinct individual (FALSE, the default), or if each row of the data frame represents different time epochs for only one individual (TRUE). In the former case the result will have one curve for each row in <code>newdata</code> , in the latter only a single curve will be produced.                                                                                                                                         |
| <code>conf.int</code>     | the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>se.fit</code>       | a logical value indicating whether standard errors should be computed. Default is TRUE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>type,vartype</code> | a character string specifying the type of survival curve. Possible values are "aalen", "efron", or "kalbfleisch-prentice" (only the first two characters are necessary). The default is to match the computation used in the Cox model. The Nelson-Aalen-Breslow estimate for <code>ties='breslow'</code> , the Efron estimate for <code>ties='efron'</code> and the Kalbfleisch-Prentice estimate for a discrete time model <code>ties='exact'</code> . Variance estimates are the Aalen-Link-Tsiatis, Efron, and Greenwood. The default will be the Efron estimate for <code>ties='efron'</code> and the Aalen estimate otherwise. |
| <code>conf.type</code>    | One of "none", "plain", "log" (the default), or "log-log". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals <code>curve +- k *se(curve)</code> , where <code>k</code> is determined from <code>conf.int</code> . The log option calculates intervals based on the cumulative hazard or <code>log(survival)</code> . The last option bases intervals on the log hazard or <code>log(-log(survival))</code> .                                                                                                |

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| censor    | if FALSE time points at which there are no events (only censoring) are not included in the result.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| id        | optional variable name of subject identifiers. If this is present, then each group of rows with the same subject id represents the covariate path through time of a single subject, and the result will contain one curve per subject. If the coxph fit had strata then that must also be specified in newdata. If missing, then each individual row of newdata is presumed to represent a distinct subject and there will be nrow(newdata) times the number of strata curves in the result (one for each strata/subject combination). result.               |
| newstrata | if the original coxph model had strata, should the predictions be for all strata, or only for those in newdata? The default for this is TRUE if either the id or individual argument is present, as these require strata for the resulting curves to make sense. Otherwise the default is FALSE, which means to ignore any strata variable in the newdata data set, and produce predicted survivals for the entire set of strata in the original model. In this case some components of the output will be matrices with one column for each row of newdata. |
| na.action | the na.action to be used on the newdata argument                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ...       | for future methods                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Details

Serious thought has been given to removing the ‘default’ for newdata, which is to use a single “psuedo” subject with covariate values equal to the means of the data set. The resulting curve(s) almost never make sense. It remains due to the unwarranted attachment to the option shown by some users and by other packages. Two particularly egregious examples are factor variables and interactions. Suppose one were studying interspecies transmission of a virus, and the data set has a factor variable with levels (“pig”, “chicken”) and about equal numbers of observations for each. The “mean” covariate level will be 1/2 – is this a flying pig? As to interactions assume data with sex coded as 0/1, ages ranging from 50 to 80, and a model with age\*sex. The “mean” value for the age:sex interaction term will be about 30, a value that does not occur in the data.

Users are strongly advised to use the newdata argument. Note that this data set needs to contain values for the main effects but not for any interaction terms.

When the original model contains time-dependent covariates, then the path of that covariate through time needs to be specified in order to obtain a predicted curve. This requires newdata to contain multiple lines for each hypothetical subject which gives the covariate values, time interval, and strata for each line (a subject can change strata), along with an id variable which demarks which rows belong to each subject. The time interval must have the same (start, stop, status) variables as the original model: although the status variable is not used and thus can be set to a dummy value of 0 or 1, it is necessary for the variables to be recognized as a Surv object. Last, although predictions with a time-dependent covariate path can be useful, it is very easy to create a prediction that is senseless. Users are encouraged to seek out a text that discusses the issue in detail.

When all the coefficients are zero, the Kalbfleisch-Prentice estimator reduces to the Kaplan-Meier, the Aalen estimate to the exponential of Nelson’s cumulative hazard estimate, and the Efron estimate to the Fleming-Harrington estimate of survival. The variances of the curves from a Cox model are larger than these non-parametrec estimates, however, due to the variance of the coefficients.

See [survfit](#) for more details about the counts (number of events, number at risk, etc.)

The censor argument was fixed at FALSE in earlier versions of the code and not made available to the user. The default argument is sensible in most instances — and causes the familiar + sign to appear on plots — it is not sensible for time dependent covariates since it may lead to a large number of spurious marks.

### Value

an object of class "survfit". See `survfit.object` for details. Methods defined for `survfit` objects are `print`, `plot`, `lines`, and `points`.

**survfit.formula***Compute a Survival Curve for Censored Data***Description**

Computes an estimate of a survival curve for censored data using either the Kaplan-Meier or the Fleming-Harrington method. For competing risks data it computes the cumulative incidence curve.

**Usage**

```

S3 method for class 'formula'
survfit(formula, data, weights, subset, na.action,
 etype, id, istate, ...)

```

**Arguments**

|                  |                                                                                                                                                                                                                                                                                                                                       |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>formula</b>   | a formula object, which must have a <code>Surv</code> object as the response on the left of the <code>~</code> operator and, if desired, terms separated by <code>+</code> operators on the right. One of the terms may be a <code>strata</code> object. For a single survival curve the right hand side should be <code>~ 1</code> . |
| <b>data</b>      | a data frame in which to interpret the variables named in the formula, <code>subset</code> and <code>weights</code> arguments.                                                                                                                                                                                                        |
| <b>weights</b>   | The weights must be nonnegative and it is strongly recommended that they be strictly positive, since zero weights are ambiguous, compared to use of the <code>subset</code> argument.                                                                                                                                                 |
| <b>subset</b>    | expression saying that only a subset of the rows of the data should be used in the fit.                                                                                                                                                                                                                                               |
| <b>na.action</b> | a missing-data filter function, applied to the model frame, after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .                                                                                                                                                                      |
| <b>etype</b>     | a variable giving the type of event. This has been superseded by multi-state <code>Surv</code> objects; see example below.                                                                                                                                                                                                            |
| <b>id</b>        | identifies individual subjects, when a given person can have multiple lines of data.                                                                                                                                                                                                                                                  |
| <b>istate</b>    | for multi-state models, identifies the initial state of each subject                                                                                                                                                                                                                                                                  |
| <b>...</b>       | The following additional arguments are passed to internal functions called by <code>survfit</code> .                                                                                                                                                                                                                                  |

**type** a character string specifying the type of survival curve. Possible values are "kaplan-meier", "fleming-harrington" or "fh2" if a formula is given.

This is ignored for competing risks or when the Turnbull estimator is used.

**error** a character string specifying the error. Possible values are "greenwood" for the Greenwood formula or "tsiatis" for the Tsiatis formula, (only the first character is necessary).

**conf.type** One of "none", "plain", "log" (the default), or "log-log". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals curve  $\pm k * se(curve)$ , where  $k$  is determined from **conf.int**. The log option calculates intervals based on the cumulative hazard or  $\log(survival)$ . The last option bases intervals on the log hazard or  $\log(-\log(survival))$ .

**conf.lower** a character string to specify modified lower limits to the curve, the upper limit remains unchanged. Possible values are "usual" (unmodified), "peto", and "modified". The modified lower limit is based on an "effective n" argument. The confidence bands will agree with the usual calculation at each death time, but unlike the usual bands the confidence interval becomes wider at each censored observation. The extra width is obtained by multiplying the usual variance by a factor  $m/n$ , where  $n$  is the number currently at risk and  $m$  is the number at risk at the last death time. (The bands thus agree with the un-modified bands at each death time.) This is especially useful for survival curves with a long flat tail.

The Peto lower limit is based on the same "effective n" argument as the modified limit, but also replaces the usual Greenwood variance term with a simple approximation. It is known to be conservative.

**start.time** numeric value specifying a time to start calculating survival information. The resulting curve is the survival conditional on surviving to **start.time**.

**conf.int** the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.

**se.fit** a logical value indicating whether standard errors should be computed. Default is TRUE.

## Details

The estimates used are the Kalbfleisch-Prentice (Kalbfleisch and Prentice, 1980, p.86) and the Tsiatis/Link/Breslow, which reduce to the Kaplan-Meier and Fleming-Harrington estimates, respectively, when the weights are unity.

The Greenwood formula for the variance is a sum of terms  $d/(n*(n-m))$ , where  $d$  is the number of deaths at a given time point,  $n$  is the sum of weights for all individuals still at risk at that time, and  $m$  is the sum of weights for the deaths at that time. The justification is based on a binomial argument when weights are all equal to one; extension to the weighted case is ad hoc. Tsiatis (1981) proposes a sum of terms  $d/(n*n)$ , based on a counting process argument which includes the weighted case.

The two variants of the F-H estimate have to do with how ties are handled. If there were 3 deaths out of 10 at risk, then the first increments the hazard by  $3/10$  and the second by  $1/10 + 1/9 + 1/8$ . For the first method  $S(t) = \exp(H)$ , where  $H$  is the Nelson-Aalen cumulative hazard estimate, whereas the fh2 method will give results  $S(t)$  results closer to the Kaplan-Meier.

When the data set includes left censored or interval censored data (or both), then the EM approach of Turnbull is used to compute the overall curve. When the baseline method is the Kaplan-Meier, this is known to converge to the maximum likelihood estimate.

The cumulative incidence curve is an alternative to the Kaplan-Meier for competing risks data. For instance, in patients with MGUS, conversion to an overt plasma cell malignancy occurs at a nearly constant rate among those still alive. A Kaplan-Meier estimate, treating death due to other causes as censored, gives a 20 year cumulate rate of 33% for the 241 early patients of Kyle. This estimates the incidence of conversion if all other causes of death were removed, which is an unrealistic assumption given the mean starting age of 63 and a median follow up of over 21 years.

The CI estimate, on the other hand, estimates the total number of conversions that will actually occur. Because the population is older, this is much smaller than the KM, 22% at 20 years for Kyle's data. If there were no censoring, then  $\text{CI}(t)$  could very simply be computed as total number of patients with progression by time  $t$  divided by the sample size  $n$ .

### **Value**

an object of class "survfit". See *survfit.object* for details. Methods defined for *survfit* objects are *print*, *plot*, *lines*, and *points*.

**survfit.object***Survival Curve Object***Description**

This class of objects is returned by the `survfit` class of functions to represent a fitted survival curve.

Objects of this class have methods for the functions `print`, `summary`, `plot`, `points` and `lines`. The `print.survfit` method does more computation than is typical for a print method and is documented on a separate page. Class of objects that represent a fitted survival curve.

**Arguments**

- |                      |                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------|
| <code>n</code>       | total number of subjects in each curve.                                                    |
| <code>time</code>    | the time points at which the curve has a step.                                             |
| <code>n.risk</code>  | the number of subjects at risk at <code>t</code> .                                         |
| <code>n.event</code> | the number of events that occur at time <code>t</code> .                                   |
| <code>n.enter</code> | for counting process data only, the number of subjects that enter at time <code>t</code> . |

|                   |                                                                                                                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>n.censor</b>   | for counting process data only, the number of subjects who exit the risk set, without an event, at time t. (For right censored data, this number can be computed from the successive values of the number at risk).                                                                                   |
| <b>surv</b>       | the estimate of survival at time t+0. This may be a vector or a matrix.                                                                                                                                                                                                                               |
| <b>std.err</b>    | the standard error of the cumulative hazard or -log(survival).                                                                                                                                                                                                                                        |
| <b>upper</b>      | upper confidence limit for the survival curve.                                                                                                                                                                                                                                                        |
| <b>lower</b>      | lower confidence limit for the survival curve.                                                                                                                                                                                                                                                        |
| <b>strata</b>     | if there are multiple curves, this component gives the number of elements of the time etc. vectors corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves.                                                                                |
| <b>start.time</b> | the value specified for the <b>start.time</b> argument, if it was used in the call.                                                                                                                                                                                                                   |
| <b>n.all</b>      | for counting process data, and any time that the <b>start.time</b> argument was used, this contains the total number of observations that were available. Not all may have been used in creating the curve, in which case this value will be larger than n above. of observations that were available |
| <b>conf.type</b>  | the approximation used to compute the confidence limits.                                                                                                                                                                                                                                              |
| <b>conf.int</b>   | the level of the confidence limits, e.g. 90 or 95%.                                                                                                                                                                                                                                                   |
| <b>na.action</b>  | the returned value from the <b>na.action</b> function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values.                                                                                                                          |
| <b>call</b>       | an image of the call that produced the object.                                                                                                                                                                                                                                                        |
| <b>type</b>       | type of survival censoring.                                                                                                                                                                                                                                                                           |

## Structure

The following components must be included in a legitimate **survfit** object.

## Subscripts

Survfit objects that contain multiple survival curves can be subscripted. This is most often used to plot a subset of the curves. Usually a single subscript will be used. In one particular case – survival curves for multiple covariate values, from a Cox model that includes a **strata** statement – there is a matrix of curves and 2 subscripts may be used. (In this case **summary.survfit** will also print the data as a matrix).

## See Also

[plot.survfit](#), [summary.survfit](#), [print.survfit](#), [survfit](#).

## Description

This program is mainly supplied to allow other packages to invoke the **survfit.coxph** function at a ‘data’ level rather than a ‘user’ level. It does no checks on the input data that is provided, which can lead to unexpected errors if that data is wrong.

### Usage

```
survfitcoxph.fit(y, x, wt, x2, risk, newrisk, strata, se.fit, survtype,
 vartype, varmat, id, y2, strata2, unlist=TRUE)
```

### Arguments

|          |                                                                                                                                                                                                                                          |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y        | the response variable used in the Cox model. (Missing values removed of course.)                                                                                                                                                         |
| x        | covariate matrix used in the Cox model                                                                                                                                                                                                   |
| wt       | weight vector for the Cox model. If the model was unweighted use a vector of 1s.                                                                                                                                                         |
| x2       | matrix describing the hypothetical subjects for which a curve is desired. Must have the same number of columns as x.                                                                                                                     |
| risk     | the risk score $\exp(X \beta)$ from the fitted Cox model. If the model had an offset, include it in the argument to exp.                                                                                                                 |
| newrisk  | risk scores for the hypothetical subjects                                                                                                                                                                                                |
| strata   | strata variable used in the Cox model. This will be a factor.                                                                                                                                                                            |
| se.fit   | if TRUE the standard errors of the curve(s) are returned                                                                                                                                                                                 |
| survtype | 1=Kalbfleish-Prentice, 2=Nelson-Aalen, 3=Efron. It is usual to match this to the approximation for ties used in the coxph model: KP for ‘exact’, N-A for ‘breslow’ and Efron for ‘efron’.                                                |
| vartype  | 1=Greenwood, 2=Aalen, 3=Efron                                                                                                                                                                                                            |
| varmat   | the variance matrix of the coefficients                                                                                                                                                                                                  |
| id       | optional; if present and not NULL this should be a vector of identifiers of length nrow(x2). A non-null value signifies that x2 contains time dependent covariates, in which case this identifies which rows of x2 go with each subject. |
| y2       | survival times, for time dependent prediction. It gives the time range (time1,time2] for each row of x2. Note: this must be a Surv object and thus contains a status indicator, which is never used in the routine, however.             |
| strata2  | vector of strata indicators for x2. This must be a factor.                                                                                                                                                                               |
| unlist   | if FALSE the result will be a list with one element for each strata. Otherwise the strata are “unpacked” into the form found in a survfit object.                                                                                        |

### Value

a list containing nearly all the components of a survfit object. All that is missing is to add the confidence intervals, the type of the original model’s response (as in a coxph object), and the class.

### Note

The source code for both this function and survfit.coxph is written using noweb. For complete documentation see the `inst/sourcecode.pdf` file.

*O'Brien's Test for Association of a Single Variable with Survival*

## Description

Peter O'Brien's test for association of a single variable with survival This test is proposed in Biometrics, June 1978.

## Usage

```
survobrien(formula, data, subset, na.action, transform)
```

## Arguments

|                  |                                                                                                                                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>formula</b>   | a valid formula for a cox model.                                                                                                                                                                                                          |
| <b>data</b>      | a data.frame in which to interpret the variables named in the formula, or in the subset and the weights argument.                                                                                                                         |
| <b>subset</b>    | expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.                                                                                                               |
| <b>na.action</b> | a missing-data filter function. This is applied to the model.frame after any subset argument has been used. Default is options()\$na.action.                                                                                              |
| <b>transform</b> | the transformation function to be applied at each time point. The default is O'Brien's suggestion logit(tr) where tr = (rank(x)- 1/2)/ length(x) is the rank shifted to the range 0-1 and logit(x) = log(x/(1-x)) is the logit transform. |

## Value

a new data frame. The response variables will be column names returned by the Surv function, i.e., "time" and "status" for simple survival data, or "start", "stop", "status" for counting process data. Each individual event time is identified by the value of the variable .strata.. Other variables retain their original names. If a predictor variable is a factor or is protected with I(), it is retained as is. Other predictor variables have been replaced with time-dependent logit scores.

The new data frame will have many more rows than the original data, approximately the original number of rows \* number of deaths/2.

## Method

A time-dependent cox model can now be fit to the new data. The univariate statistic, as originally proposed, is equivalent to single variable score tests from the time-dependent model. This equivalence is the rationale for using the time dependent model as a multivariate extension of the original paper.

In O'Brien's method, the x variables are re-ranked at each death time. A simpler method, proposed by Prentice, ranks the data only once at the start. The results are usually similar.

## Note

A prior version of the routine returned new time variables rather than a strata. Unfortunately, that strategy does not work if the original formula has a strata statement. This new data set will be the same size, but the coxph routine will process it slightly faster.

## Examples

```
xx <- survobrien(Surv(futime, fustat) ~ age + factor(rx) + I(ecog.ps),
 data=ovarian)
coxph(Surv(time, status) ~ age + strata(.strata.), data=xx)
```

survreg

*Regression for a Parametric Survival Model*

## Description

Fit a parametric survival regression model. These are location-scale models for an arbitrary transform of the time variable; the most common cases use a log transformation, leading to accelerated failure time models.

## Usage

```
survreg(formula, data, weights, subset,
 na.action, dist="weibull", init=NULL, scale=0,
 control, parms=NULL, model=FALSE, x=FALSE,
 y=TRUE, robust=FALSE, score=FALSE, ...)
```

## Arguments

|           |                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| formula   | a formula expression as for other regression models. The response is usually a survival object as returned by the Surv function. See the documentation for Surv, lm and formula for details.                                                                                                                                                                                                   |
| data      | a data frame in which to interpret the variables named in the formula, weights or the subset arguments.                                                                                                                                                                                                                                                                                        |
| weights   | optional vector of case weights                                                                                                                                                                                                                                                                                                                                                                |
| subset    | subset of the observations to be used in the fit                                                                                                                                                                                                                                                                                                                                               |
| na.action | a missing-data filter function, applied to the model.frame, after any subset argument has been used. Default is options()\$na.action.                                                                                                                                                                                                                                                          |
| dist      | assumed distribution for y variable. If the argument is a character string, then it is assumed to name an element from <a href="#">survreg.distributions</a> . These include "weibull", "exponential", "gaussian", "logistic", "lognormal" and "loglogistic". Otherwise, it is assumed to be a user defined list conforming to the format described in <a href="#">survreg.distributions</a> . |
| parms     | a list of fixed parameters. For the t-distribution for instance this is the degrees of freedom; most of the distributions have no parameters.                                                                                                                                                                                                                                                  |

|                          |                                                                                                                                                                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>init</code>        | optional vector of initial values for the parameters.                                                                                                                                                                                  |
| <code>scale</code>       | optional fixed value for the scale. If set to $<=0$ then the scale is estimated.                                                                                                                                                       |
| <code>control</code>     | a list of control values, in the format produced by <a href="#">survreg.control</a> . The default value is <code>survreg.control()</code>                                                                                              |
| <code>model, x, y</code> | flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments. |
| <code>score</code>       | return the score vector. (This is expected to be zero upon successful convergence.)                                                                                                                                                    |
| <code>robust</code>      | Use robust 'sandwich' standard errors, based on independence of individuals if there is no <code>cluster()</code> term in the formula, based on independence of clusters if there is.                                                  |
| <code>...</code>         | other arguments which will be passed to <code>survreg.control</code> .                                                                                                                                                                 |

### Value

an object of class `survreg` is returned.

### See Also

[survreg.object](#), [survreg.distributions](#), [pspline](#), [frailty](#), [ridge](#)

### Examples

```
Fit an exponential model: the two fits are the same
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian, dist='weibull',
 scale=1)
survreg(Surv(futime, fustat) ~ ecog.ps + rx, ovarian,
 dist="exponential")

#
A model with different baseline survival shapes for two groups, i.e.,
two different scales
survreg(Surv(time, status) ~ ph.ecog + age + strata(sex), lung)

There are multiple ways to parameterize a Weibull distribution. The survreg
function imbeds it in a general location-scale family, which is a
different parameterization than the rweibull function, and often leads
to confusion.
survreg's scale = 1/(rweibull shape)
survreg's intercept = log(rweibull scale)
For the log-likelihood all parameterizations lead to the same value.
y <- rweibull(1000, shape=2, scale=5)
survreg(Surv(y)^1, dist="weibull")

Economists fit a model called 'tobit regression', which is a standard
linear regression with Gaussian errors, and left censored data.
tobinfit <- survreg(Surv(durable, durable>0, type='left') ~ age + quant,
 data=tobin, dist='gaussian')
```

---

**survreg.control** *Package options for survreg and coxph*

---

**Description**

This function checks and packages the fitting options for [survreg](#)

**Usage**

```
survreg.control(maxiter=30, rel.tolerance=1e-09,
toler.chol=1e-10, iter.max, debug=0, outer.max=10)
```

**Arguments**

|               |                                                                    |
|---------------|--------------------------------------------------------------------|
| maxiter       | maximum number of iterations                                       |
| rel.tolerance | relative tolerance to declare convergence                          |
| toler.chol    | Tolerance to declare Cholesky decomposition singular               |
| iter.max      | same as maxiter                                                    |
| debug         | print debugging information                                        |
| outer.max     | maximum number of outer iterations for choosing penalty parameters |

**Value**

A list with the same elements as the input

**See Also**

[survreg](#)

---

**survreg.distributions** *Parametric Survival Distributions*

---

**Description**

List of distributions for accelerated failure models. These are location-scale families for some transformation of time. The entry describes the cdf  $F$  and density  $f$  of a canonical member of the family.

**Usage**

[survreg.distributions](#)

## Format

There are two basic formats, the first defines a distribution de novo, the second defines a new distribution in terms of an old one.

|                          |                                                                                                            |
|--------------------------|------------------------------------------------------------------------------------------------------------|
| name:                    | name of distribution                                                                                       |
| variance:                | function(parms) returning the variance (currently unused)                                                  |
| init(x,weights,...):     | Function returning an initial estimate of the mean and variance (used for initial values in the iteration) |
| density(x,parms):        | Function returning a matrix with columns $F$ , $1 - F, f, f'/f, f''/f$                                     |
| quantile(p,parms):       | Quantile function                                                                                          |
| scale:                   | Optional fixed value for the scale parameter                                                               |
| parms:                   | Vector of default values and names for any additional parameters                                           |
| deviance(y,scale,parms): | Function returning the deviance for a saturated model; used only for deviance residuals.                   |

and to define one distribution in terms of another

|         |                                          |
|---------|------------------------------------------|
| name:   | name of distribution                     |
| dist:   | name of parent distribution              |
| trans:  | transformation (eg log)                  |
| dtrans: | derivative of transformation             |
| itrans: | inverse of transformation                |
| scale:  | Optional fixed value for scale parameter |

## Details

There are four basic distributions: extreme, gaussian, logistic and t. The last three are parametrised in the same way as the distributions already present in R. The extreme value cdf is

$$F = 1 - e^{-e^t}.$$

When the logarithm of survival time has one of the first three distributions we obtain respectively weibull, lognormal, and loglogistic. The location-scale parameterization of a Weibull distribution found in survreg is not the same as the parameterization of [rweibull](#).

The other predefined distributions are defined in terms of these. The exponential and rayleigh distributions are Weibull distributions with fixed scale of 1 and 0.5 respectively, and loggaussian is a synonym for lognormal.

For speed parts of the three most commonly used distributions are hardcoded in C; for this reason the elements of survreg.distributions with names of "Extreme value", "Logistic" and "Gaussian" should not be modified. (The order of these in the list is not important, recognition is by name.) As an alternative to modifying survreg.distributions a new distribution can be specified as a separate list. This is the preferred method of addition and is illustrated below.

## Examples

```

time transformation
survreg(Surv(time, status) ~ ph.ecog + sex, dist='weibull', data=lung)
change the transformation to work in years
intercept changes by log(365), everything else stays the same
my.weibull <- survreg.distributions$weibull
my.weibull$trans <- function(y) log(y/365)
my.weibull$itrans <- function(y) 365*exp(y)
survreg(Surv(time, status) ~ ph.ecog + sex, lung, dist=my.weibull)

Weibull parametrisation
y<-rweibull(1000, shape=2, scale=5)
survreg(Surv(y)~1, dist="weibull")
survreg parameters are scale=1/shape, intercept=log(scale)

Cauchy fit
mycauchy <- list(name='Cauchy',
 init= function(x, weights, ...)
 c(median(x), mad(x)),
 density= function(x, parms) {
 temp <- 1/(1 + x^2)
 cbind(.5 + atan(x)/pi, .5+ atan(-x)/pi,
 temp/pi, -2 *x*temp, 2*temp*(4*x^2*temp -1))
 },
 quantile= function(p, parms) tan((p-.5)*pi),
 deviance= function(...) stop('deviance residuals not defined')
)
survreg(Surv(log(time), status) ~ ph.ecog + sex, lung, dist=mycauchy)

```

## survreg.object

*Parametric Survival Model Object*

## Description

This class of objects is returned by the `survreg` function to represent a fitted parametric survival model. Objects of this class have methods for the functions `print`, `summary`, `predict`, and `residuals`.

## COMPONENTS

The following components must be included in a legitimate `survreg` object.

**coefficients** the coefficients of the `linear.predictors`, which multiply the columns of the model matrix. It does not include the estimate of error (`sigma`). The names of the coefficients are the names of the single-degree-of-freedom effects (the columns of the model matrix). If the model is over-determined there will be missing values in the coefficients corresponding to non-estimable coefficients.

**icof** coefficients of the baseline model, which will contain the intercept and `log(scale)`, or multiple scale factors for a stratified model.

**var** the variance-covariance matrix for the parameters, including the `log(scale)` parameter(s).

**loglik** a vector of length 2, containing the log-likelihood for the baseline and full models.

**iter** the number of iterations required

**linear.predictors** the linear predictor for each subject.

**df** the degrees of freedom for the final model. For a penalized model this will be a vector with one element per term.

**scale** the scale factor(s), with length equal to the number of strata.

**idf** degrees of freedom for the initial model.

**means** a vector of the column means of the coefficient matrix.

**dist** the distribution used in the fit.

The object will also have the following components found in other model results (some are optional): **linear predictors**, **weights**, **x**, **y**, **model**, **call**, **terms** and **formula**. See **lm**.

## See Also

[survreg](#), [lm](#)

**survregDtest**

*Verify a survreg distribution*

## Description

This routine is called by **survreg** to verify that a distribution object is valid.

## Usage

```
survregDtest(dlist, verbose = F)
```

## Arguments

- |                |                                                                                                             |
|----------------|-------------------------------------------------------------------------------------------------------------|
| <b>dlist</b>   | the list describing a survival distribution                                                                 |
| <b>verbose</b> | return a simple TRUE/FALSE from the test for validity (the default), or a verbose description of any flaws. |

## Details

If the **survreg** function rejects your user-supplied distribution as invalid, this routine will tell you why it did so.

## Value

TRUE if the distribution object passes the tests, and either FALSE or a vector of character strings if not.

## Author(s)

Terry Therneau

## See Also

## Examples

```
An invalid distribution (it should have "init =" on line 2)
survreg would give an error message
mycauchy <- list(name='Cauchy',
 init<- function(x, weights, ...)
 c(median(x), mad(x)),
 density= function(x, parms) {
 temp <- 1/(1 + x^2)
 cbind(.5 + atan(temp)/pi, .5+ atan(-temp)/pi,
 temp/pi, -2 *x*temp, 2*temp^2*(4*x^2*temp -1))
 },
 quantile= function(p, parms) tan((p-.5)*pi),
 deviance= function(...) stop('deviance residuals not defined')
)

survregDtest(mycauchy, TRUE)
```

## survSplit

*Split a survival data set at specified times*

## Description

Given a survival data set and a set of specified cut times, split each record into multiple subrecords at each cut time. The new data set will be in ‘counting process’ format, with a start time, stop time, and event status for each record.

## Usage

```
survSplit(data, cut, end, event, start, id = NULL, zero = 0,
 episode=NULL)
```

## Arguments

|         |                                                                                                                       |
|---------|-----------------------------------------------------------------------------------------------------------------------|
| data    | data frame                                                                                                            |
| cut     | vector of timepoints to cut at                                                                                        |
| end     | character string with name of event time variable                                                                     |
| event   | character string with name of censoring indicator                                                                     |
| start   | character string with name of start time variable (will be created if it does not exist)                              |
| id      | character string with name of new id variable to create (optional)                                                    |
| zero    | If start doesn’t already exist, this is the time that the original records start.<br>May be a vector or single value. |
| episode | character string with name of new episode variable (optional)                                                         |

## Details

The function also works when the original data are in counting-process format, but the id and episode options are of little use in this context.

**Value**

New, longer, data frame.

**See Also**

[Surv](#), [cut](#), [reshape](#)

**Examples**

```
aml3<-survSplit(aml,cut=c(5,10,50),end="time",start="start",
 event="status",episode="i")

summary(aml)
summary(aml3)

coxph(Surv(time,status)~x,data=aml)
the same
coxph(Surv(start,time,status)~x,data=aml3)

aml4<-survSplit(aml3,cut=20,end="time",start="start", event="status")
coxph(Surv(start,time,status)~x,data=aml4)
```

**tcut**

*Factors for person-year calculations*

**Description**

Attaches categories for person-year calculations to a variable without losing the underlying continuous representation

**Usage**

```
tcut(x, breaks, labels, scale=1)
```

**Arguments**

|               |                                                       |
|---------------|-------------------------------------------------------|
| <b>x</b>      | numeric/date variable                                 |
| <b>breaks</b> | breaks between categories, which are right-continuous |
| <b>labels</b> | labels for categories                                 |
| <b>scale</b>  | Multiply <b>x</b> and <b>breaks</b> by this.          |

**Value**

An object of class **tcut**

**See Also**

[cut](#), [pyears](#)

## Examples

```

mdy.date <- function(m,d,y)
 as.Date(paste(ifelse(y<100, y+1900, y), m, d, sep='/'))
temp1 <- mdy.date(6,6,36)
temp2 <- mdy.date(6,6,55)# Now compare the results from person-years
#
temp.age <- tcut(temp2-temp1, floor(c(-1, (18:31 * 365.24))),
 labels=c('0-18', paste(18:30, 19:31, sep='-')))
temp.yr <- tcut(temp2, mdy.date(1,1,1954:1965), labels=1954:1964)
temp.time <- 3700 #total days of fu
py1 <- pyears(temp.time ~ temp.age + temp.yr, scale=1) #output in days
py1

```

tobin

*Tobin's Tobit data*

## Description

Economists fit a parametric censored data model called the ‘tobit’. These data are from Tobin’s original paper.

## Usage

```
tobin
```

## Format

A data frame with 20 observations on the following 3 variables.

**durable** Durable goods purchase  
**age** Age in years  
**quant** Liquidity ratio (x 1000)

## Source

J Tobin (1958), Estimation of relationships for limited dependent variables. *Econometrica* **26**, 24–36.

## Examples

```

tfit <- survreg(Surv(durable, durable>0, type='left') ~age + quant,
 data=tobin, dist='gaussian')

predict(tfit,type="response")

```

|    |                                  |
|----|----------------------------------|
| tt | <i>Mark time transform terms</i> |
|----|----------------------------------|

## Description

This is a dummy function, used to mark terms in the formula argument of `coxph` for time dependent transformations.

## Usage

```
tt(x)
```

## Arguments

|   |                    |
|---|--------------------|
| x | a numeric variable |
|---|--------------------|

## Details

This function is not used outside of `coxph`, see that help page for an example.

## Value

x, unchanged

## See Also

[coxph](#)

|                   |                                                                      |
|-------------------|----------------------------------------------------------------------|
| untangle.specials | <i>Help Process the ‘specials’ Argument of the ‘terms’ Function.</i> |
|-------------------|----------------------------------------------------------------------|

## Description

Given a `terms` structure and a desired special name, this returns an index appropriate for subscripting the `terms` structure and another appropriate for the data frame.

## Usage

```
untangle.specials(tt, special, order=1)
```

## Arguments

|         |                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------|
| tt      | a <code>terms</code> object.                                                                          |
| special | the name of a special function, presumably used in the <code>terms</code> object.                     |
| order   | the order of the desired terms. If set to 2, interactions with the special function will be included. |

**Value**

a list with two components:

- |       |                                                                                                                                                  |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| vars  | a vector of variable names, as would be found in the data frame, of the specials.                                                                |
| terms | a numeric vector, suitable for subscripting the terms structure, that indexes the terms in the expanded model formula which involve the special. |

**Examples**

```
formula<-Surv(tt,ss)~x+z*strata(id)
tms<-terms(formula,specials="strata")
the specials attribute
attr(tms,"specials")
main effects
untangle.specials(tms,"strata")
and interactions
untangle.specials(tms,"strata",order=1:2)
```

---

uspop2

*Projected US Population*

---

**Description**

US population by age and sex, for 2000 through 2020

**Usage**

```
data(uspop2)
```

**Format**

The data is a matrix with dimensions age, sex, and calendar year. Age goes from 0 through 100, where the value for age 100 is the total for all ages of 100 or greater.

**Details**

This data is often used as a "standardized" population for epidemiology studies.

**Source**

NP2008\_D1: Projected Population by Single Year of Age, Sex, Race, and Hispanic Origin for the United States: July 1, 2000 to July 1, 2050, [www.census.gov/population/projections](http://www.census.gov/population/projections).

**See Also**

[uspop](#)

### Examples

```
us50 <- uspop2[51:101,, "2000"] #US 2000 population, 50 and over
age <- as.integer(dimnames(us50)[[1]])
smat <- model.matrix(~ factor(floor(age/5)) -1)
ustot <- t(smat) %*% us50 #totals by 5 year age groups
temp <- c(50,55, 60, 65, 70, 75, 80, 85, 90, 95)
dimnames(ustot) <- list(c(paste(temp, temp+4, sep="-"), "100+"),
c("male", "female"))
```

veteran

*Veterans' Administration Lung Cancer study*

### Description

Randomised trial of two treatment regimens for lung cancer. This is a standard survival analysis data set.

### Usage

veteran

### Format

|           |                                           |
|-----------|-------------------------------------------|
| trt:      | 1=standard 2=test                         |
| celltype: | 1=squamous, 2=smallcell, 3=adeno, 4=large |
| time:     | survival time                             |
| status:   | censoring status                          |
| karno:    | Karnofsky performance score (100=good)    |
| diagtime: | months from diagnosis to randomisation    |
| age:      | in years                                  |
| prior:    | prior therapy 0=no, 1=yes                 |
